## Abstract

The aim of this thesis is to find the expected total compensation cost the insurance company (VÍS) needs to pay due to car accidents. Information are based on postal codes and the compensation cost is examined for each postal code in the country using a Poisson model and a gamma model, respectively. One of the main goals was to evaluate whether the residence of policyholders influence the result, by using spatial factor, one for each postal code. Another goal was to see if the results are improved by having temporal factor included in the model. Also, to improve the spatial factor, postal codes were categorized into postal category matrix where each category describes the type of region.

To examine the expected total compensation cost it is necessary to find the expected frequency of claims per policy year and the expected total claim size per policy year. These factors are examined per each postal code in the country. The expected compensation cost is calculated from the combination of those two models.

Data for mandatory liability insurances for vehicles are divided into three main categories, property loss, bodily injury and drivers accident insurance. In this study only results for property loss are given for one risk category over 16 year period.

The main result is that the claim frequency per policy year depends on the residence of policyholders. The number of claims are higher in the capital area than in the countryside. The spatial factor is very effective but the temporal factor influences much less. Nonetheless, it was decided to include the temporal factor in the model since it did not make the model less qualified. Also, there is a possibility of years with higher number of claims which would support the inclusion of the temporal factor.

Results for the total claim size show that the expected claim sizes are independent of the the residence of policyholders. The total claim size is similar no matter which part of the country is examined. Originally the model included both temporal factor and spatial factor but the spatial factor was taken out of the model since it did not influence the results. Nonetheless there are always some spatial effects from the postal category matrix. The temporal factor on the other hand has a substantial influence on the total claim size even though the data has been brought to present worth.

The expected total compensation cost the insurance company needs to pay is in context to the earlier mentioned results. The cost is highest in Reykjavík and the neighborhood of Reykjavík, gets lower when the countryside is examined but raises a bit at and around large urban regions. According to these results, it is justified that pricing of insurance would depend on the residence of policyholders.

## Ágrip

Markmið pessa verkefnis er að finna út væntanlegan heildarkostnað sem tryggingafélagið (VÍS) barf að greiða í bætur vegna bílslysa. Upplýsingar eru byggðar á póstnúmerum og er kostnaðurinn skoðaður fyrir hvert póstnúmer landsins. Hugmyndin er að meta hvort lögheimili vátryggingartaka hafi áhrif á niðurstöðuna með pví að bæta landfræðilegum bætti í líkanið. Einnig var skoðað hvort bæta megi niðurstöður með pví að hafa tímapátt í líkaninu. Póstnúmerin voru flokkuð í stærri póstnúmeraflokka til að auka gæði landfræðilega báttarins.

Til að skoða væntanlegan kostnað barf fyrst að finna væntanlegan fjölda tjóna á hvert skírteinisár og væntanlega heildarstærð tjóna á hvert skírteinisár. Pessir tveir bættir eru skoðaðir fyrir hvert póstnúmer með bví að nota Poisson líkan fyrir væntanlegan fjölda og gamma líkan fyrir heildarstærð. Væntanlegur kostnaður er reiknaður út frá sameiningu á bessum tveim líkönum.

Gögnum fyrir lögboðnar ábyrgðartryggingar vegna ökutækja er skipt í prennt, munatjón, líkamstjón og slysatrygging ökumanns og eiganda. Aðeins eru gefnar niðurstöður fyrir munatjón í bessari ritgerð og fyrir einn áhættuflokk en gögnin ná yfir 16 ára tímabil.

Helstu niðurstöður eru að fjöldi tjóna á hvert skírteinisár er háður lögheimili vátryggingartaka. Fjöldi tjóna er meiri á höfuðborgarsvæðinu en á landsbyggðinni. Landfræðilegi pátturinn er áhrifamikill en tímabátturinn hefur mun minni áhrif. Engu að síður var ákveðið að hafa tímabáttinn í líkaninu bar sem bað skerti ekki gæði líkansins. Einnig er möguleiki á tjónapyngri árum sem styður bað að nota tímabáttinn.

Niðurstöður fyrir heildarstærð tjóna eru að lögheimili vátryggingartaka hefur lítil áhrif á heildar stærð tjóna. Póstnúmerapátturinn hefur lítil áhrif, en engu að síður hafa póstnúmeraflokkarnir áhrif á niðurstöðuna. Heildarstærð tjóna er svipuð sama á hvaða landshluta er horft. Í upphafi innihélt líkanið bæði tímapátt og landfræðilegan pátt en landfræðilegi bátturinn var tekinn út úr líkaninu bar sem hann hafði mjög lítil áhrif. Tímapátturinn hefur aftur á móti mikil áhrif prátt fyrir ad gögnin hafi verið núvirt.

Væntanlegur heildarkostnaður sem tryggingafélagið parf að greiða í bætur er í samræmi við niðurstöður sem búið er að greina frá. Kostnaðurinn er mestur í Reykjavík og nágrenni, lækkar eftir bví sem kemur út á landsbyggðina en hækkar pó aðeins í og í kringum stærri béttbýli. Kosnaðurinn er minnstur í dreifbýlum og minni béttbýlum. Samkvæmt bessum niðurstöðum er réttlætanlegt að tryggingar séu verðlagðar eftir lögheimili vátryggingartaka.

## Preface

This M.Sc. project was carried out at the Faculty of Industrial Engineering, Mechanical Engineering and Computer Science at the University of Iceland.

Special thanks goes to my supervisor, Associate Research Professor Birgir Hrafnkelsson at the Science Institute of University of Iceland, for all his time, guidance, encouragement and support throughout the study. I would also like to thank my co-advisor Professor Ólafur Pétur Pálsson at the Faculty of Industrial Engineering, Mechanical Engineering and Computer Science, for his help during the writing of this thesis.

Itm very grateful for the co-operation with Friðrik Bragason and Ragnar Ragnarsson at VÍS and also I want to thank VÍS for their financial support during the study.

Furthermore, I would like to thank my friend Oddgeir Guðmundsson for technical support. Finally, I want to thank may family, friends and my partner, Stefán Elfar, for their moral support and encouragement during the study and also my loving son, Arnar Geir for his inspiration.

Reykjavík, May 2010.
Erna Sigurgeirsdóttir

## Nomenclature

$\alpha \quad$ Parameter in the gamma model
$\alpha_{0} \quad$ Parameter for gamma prior distribution
$\alpha_{\phi 1}$ and $\alpha_{\phi 2}$ Parameters in the prior distribution for $\phi_{1}$ and $\phi_{2}$ in the Poisson model
$\alpha_{\zeta 1}$ and $\alpha_{\zeta 2}$ Parameters in the prior distribution for $\zeta_{1}$ and $\zeta_{2}$ in the gamma model
$\beta \quad$ Coefficient for postal categories in the Poisson model
$\beta_{0} \quad$ Parameter for gamma prior distribution
$\beta_{\phi 1}$ and $\beta_{\phi 2}$ Parameters in the prior distribution for $\phi_{1}$ and $\phi_{1}$ in the Poisson model
$\beta_{\zeta 1}$ and $\beta_{\zeta_{2}}$ Parameters in the prior distribution for $\zeta_{1}$ and $\zeta_{2}$ in the gamma model
$\eta \quad$ Coefficient for postal categories in the gamma model
$\kappa_{1}^{2}$ and $\kappa_{2}^{2}$ Hyperparameters in the gamma model
$\mu \quad$ Mean
$\nu_{r} \quad$ Parameter relative to $\sigma_{r}^{2}$ in the gamma model
$\nu_{\kappa 1}$ and $\nu_{\kappa 2}$ Parameters in the prior distribution for $\kappa_{1}^{2}$ and $\kappa_{2}^{2}$ in the gamma model $\nu_{\tau 1}$ and $\nu_{\tau 2}$ Parameters in the prior distribution for $\tau_{1}^{2}$ and $\tau_{2}^{2}$ in the Poisson model $\nu_{\varepsilon} \quad$ Parameter in the prior distribution for $\sigma_{\varepsilon}^{2}$ in the Poisson model
$\phi_{1}$ and $\phi_{2}$ Hyperparameters in the Poisson model
$\sigma_{\varepsilon, i t}^{2} \quad$ Variance constant in the Poisson model
$\sigma_{i t}^{2} \quad$ Variance in the gamma model
$\sigma_{r}^{2} \quad$ Hyperparameter in the gamma model
$\tau_{1}^{2}$ and $\tau_{2}^{2}$ Hyperparameters in the Poisson model
$\theta_{i t} \quad$ Average number of claims in region $i$ and at year $t$
$\varepsilon_{i t} \quad$ Error term in the Poisson model
$\zeta_{1}$ and $\zeta_{2}$ Hyperparameters in the gamma model
$a_{1, t} \quad$ Temporal factor in the Poisson model
$a_{2, i} \quad$ Regional factor in the Poisson model
$C \quad$ Neighborhood matrix based on the neighborhood matrix H
$d_{1, t} \quad$ Temporal factor in the gamma model
$d_{2, i} \quad$ Regional factor in the gamma model
$e_{i t} \quad$ Number of policy-years in region $i$ and at year $t$

H Neighborhood matrix
$M$ Diagonal matrix based to the neighborhood matrix H
$N_{i t} \quad$ Number of claim in region $i$ and at year $t$
$S_{r}^{2} \quad$ Parameter relative to $\sigma_{r}^{2}$ in the gamma model
$S_{\kappa 1}^{2}$ and $S_{\kappa 2}^{2}$ Parameters in the prior distribution for $\kappa_{2}^{2}$ in the gamma model
$S_{\tau 1}^{2}$ and $S_{\tau 2}^{2}$ Parameters in the prior distribution for $\tau_{1}^{2}$ and $\tau_{2}^{2}$ in the Poisson model
$S_{\varepsilon}^{2} \quad$ Parameter in the prior distribution for $\sigma_{\varepsilon}^{2}$ in the Poisson model
$S_{i t} \quad$ Total size of claim in region $i$ and at year $t$

W Unknown cost for individual claim
$x_{i}^{T} \quad$ Covariate matrix for postal categories

## 1. Introduction

The data set in this study comes from the Icelandic insurance company VíS or Vátryggingafélag Íslands hf.
Large part of cost for insurance companies are compensations because of traffic accidents. Mandatory liability insurances for vehicles are divided into three main categories,
i ) Property loss
ii ) Bodily injury
iii ) Drivers accident insurance
The risk premium charged to policyholders is determined on the basis of the claims that the company expects during the period of policy. Therefore it is important for the insurance company to have an estimate of the expected compensation for all categories. To obtain this estimate is it is necessary to examine claim frequency and claim size which are the quantities behind expected compensation cost. Interest existed at the insurance company to examine this cost down to each postal code in the country and see if there is a spatial trend in the claims. Today, the premiums for motor third party liability insurances depend on the residence of policyholders and the country is divided into a few zones. Therefore the main reason this study started was to see if a division like that is out-of date by examining the expected compensation cost for each postal code. And if it is not out-of-date, then see if it is necessary to rearrange the postal codes in the zones.

The available data are examined over a period of 16 years. Data from one risk category were analyzed. Also, only results for property loss are given in this thesis.

The first aim of this study is to estimate the expected compensation cost the insurance company needs to pay due to motor liability insurances (category i) and ii), see before page) and drivers accident insurances (category iii)). To estimate the risk premiums, Bayesian statistics are used and statistical models are built for
the expected claim frequencies and the expected total claim sizes which are used to compute the expected compensation cost. One of the main advantages of using a Bayesian statistics is that it is easy to obtain a certainity estimates for any function of the unknown parameters, such as the expected compensation cost. A Poisson model is used for the model for claim frequency and a gamma model is used for the total claim sizes. For more information about Bayesian statistics and these models see [1] and [9]. For parameter estimation Markov chain Monte Carlo (MCMC) is used, see [14] where the MCMC samplers have been implemented in Matlab. In this study the theory behind Gaussian Markov random fields (GMRF) is used to get information from neighbors, see more in [6]. In this case two neighborhood structures are constructed, one for time and other for postal codes. The neighborhood structures are described in Appendix A.

The second aim of this study is to include temporal and spatial factors and see if they improve the models. Having these two factors in the models allow for the evaluation of the time and postal codes effects. Also eight postal categories were selected depending on type of regions to improve the regional factor. These categories are similar to the zone separation the insurance company uses where the zones can be changed according to the results of the expected compensation cost.

No similar study has been conducted before here in Iceland. In Germany and Norway similar researches have been made, see [16] and [20] and this study is mainly based on those two papers. There, it is also preferred to have separate analysis of claim frequency and claim size. Similar to this study, a Poisson model is used for the expected claim frequency and a gamma model for the expected total claim sizes, and both models included spatial factors. Only spatial factor was used in those two papers but both spatial and temporal factors in this study. In both [16] and [20] claim sizes are examined per policyholder but in this study the data contains total claim size per postal code. [16] extends [20] but the before mentioned allows for dependencies between the number of claims and claim size.

### 1.1. Introduction to the thesis

The main references in this thesis are [16] and [20], that show similar researches abroad. Also [1], [9] and [7] are mainly used for the theory behind the work.

An outline of the thesis is given in the following. Chapter 2 introduces the theory behind the models used in this thesis. The basics of Bayesian inference and MCMC simulation methods are briefly summarized together with a description of the Poisson model and the gamma model. GMRF are introduced for the neighborhood structure,
the Compound collective risk model is briefly discussed and finally model comparison is addressed. In Chapter 3, a presentation of the data used in the study is given. In Chapter 4 the models used in the methods for study are expressed. They are:

- Model for claim frequency
- a Poisson model
- Model for total claim size
- a gamma model
- Expected compensation
- combination of Poisson and gamma models

Also prior distributions, the posterior distributions and conditional posterior distributions for MCMC are shown. The main results are given in Chapter 5, that is, results on expected claim frequency, expected total claim size and expected compensation.

## 2. Theory

In this chapter the theory used in this thesis is explained. It starts by giving a short introduction to the Poisson distribution and gamma distribution. Following there is an introduction to Gaussian Markov random field and the Compound collective risk model is described. Then Markov chain Monte Carlo (MCMC) simulation is briefly summarized and finally a short description of a model criteria called DIC is given.

### 2.1. The Poisson Model

Poisson distribution is a discrete probability distribution that expresses the probability of a number of events occurring in a fixed interval of time (or space) if these events occur with a known average rate and independently of the time since the last event. If the expected number of occurrences in this interval is $\lambda$, then the probability of exactly $k$ occurrences is given by the formula for the Poisson probability mass function

$$
p(k \mid \lambda)=\operatorname{Poisson}(k \mid \lambda)=\frac{1}{k!} \lambda^{k} \exp (-\lambda), \quad k \in\{0,1, \ldots, \infty\},
$$

where $\lambda>0$. Here $k$ denotes both the random variable $k$ and a particular value of $k$, which one is returned will be clear from the context. The random variable $k$ follows a Poisson distribution with parameter $\lambda$, denoted by $k \sim \operatorname{Poisson}(\lambda)$. In the Poisson model the mean and the variance of $k$ are

$$
E(k \mid \lambda)=\lambda
$$

and

$$
\operatorname{Var}(k \mid \lambda)=\lambda
$$

[1] and [18] Figure 2.1 shows the probability mass function for the Poisson distribution for four different values of $\lambda$.

Probability mass function

Figure 2.1: Poisson probability mass function with $\lambda=0.5,1,5$ and 15. The horizontal axis is $k$.

### 2.2. The gamma Model

The gamma distribution is a two-parameter family of continuous probability distributions. It has a scale parameter $\beta$ and a shape parameter $\alpha, \alpha>0$ and $\beta>0$. [18] According to [1] the gamma distribution is the conjugate prior distribution for the inverse of the normal variance and for the mean parameter of the Poisson distribution. When $\alpha>0$ the gamma integral is finite and the density function is finite. As $\alpha \rightarrow 0$ and $\beta \rightarrow 0$ a noninformative distribution is obtained in the limit.

$$
\theta \sim \operatorname{gamma}(\alpha, \beta)
$$

denotes a random variable $\theta$ that follows a gamma distribution with parameters $\alpha$ and $\beta$.

$$
p(\theta)=\operatorname{gamma}(\theta \mid \alpha, \beta)
$$

denotes the density function of the gamma distribution which is given by

$$
p(\theta)=\frac{\beta^{\alpha}}{\gamma(\alpha)} \theta^{\alpha-1} e^{-\beta \theta}, \theta>0
$$

In the gamma model the mean and variance are

$$
\begin{equation*}
\mathrm{E}(\theta)=\frac{\alpha}{\beta} \tag{2.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Var}(\theta)=\frac{\alpha}{\beta^{2}} \tag{2.2}
\end{equation*}
$$

Figure 2.2 shows the probability density function for four different values of $\alpha$.

Figure 2.2: Gamma probability density function with $\alpha=0.5,1$, 2 and 5.

### 2.3. GMRF

Gaussian Markov random fields (GMRF), also referred to as conditionally specified Gaussian models, can be useful for risk premium estimation because of the spatially interacting variables as mentioned in [20]. GMRF provides a convenient way to create a covariance matrices who describe the spatial and temporal correlation based on defining neighbors.
Let $Y=\left(Y_{1}, \ldots, Y_{n}\right)^{T}$ be an $n$ vector of random variables which follows a Gaussian distribution such that

$$
Y \sim N\left(\mu,(I-C)^{-1} M\right)
$$

where $(I-C)$ is invertible and $(I-C)^{-1} M$ is symmetric and positive definite. $C$ is an $n \times n$ matrix whose $(i, j)$-th element is $c_{i j}, c_{i j} \tau_{j}^{2}=c_{j i} \tau_{i}^{2}, c_{i i}=0, M$ is a diagonal matrix, $M=\operatorname{diag}\left(\tau_{1}^{2}, \ldots, \tau_{n}^{2}\right)$ and $\mu=\left(\mu_{1}, \ldots, \mu_{n}\right)^{T}$. Usually in models for areal data, neighboring units $i$ and $j$ are such that $c_{i j} \neq 0$ while for parts $k$ and $l$ that are far apart $c_{k l}=0,[6]$.

In this thesis the MRF are specified in the following way. Let $H$ be a matrix describing the spatial structure between $n$ units, and all of its elements are nonnegative. Let $h_{i j}$ denote the $(i, j)$-th element of $H$. Then let $M$ be a diagonal matrix such
that

$$
M_{i, j}=\frac{1}{\sum_{i=1}^{n} H_{i, j}}, \quad i=1, \ldots, n
$$

and in matrix form it will be

$$
M=\left[\begin{array}{cccc}
M_{11} & 0 & \cdots & 0 \\
0 & M_{22} & & \vdots \\
\vdots & & \ddots & 0 \\
0 & \cdots & 0 & M_{n n}
\end{array}\right]
$$

$C$ is such that

$$
C_{i, j}=\frac{H_{i, j}}{\sum_{j=1}^{n} H_{i, j}}
$$

and

$$
C=M \cdot H
$$

The covariance matrix of Y is assumed to be

$$
\Sigma=\tau^{2}(I-\phi C)^{-1} M
$$

where $\tau^{2}$ is a variance parameter.
The ordered eigenvalues of $C, \lambda_{(j)}$, is such that $\lambda_{(1)} \leq \lambda_{(2)} \leq \ldots \leq \lambda_{(n)}$. Then the determinant of $(I-\phi C)$ can be written as

$$
|I-\phi C|=\prod_{j=1}^{n}\left(1-\phi \lambda_{(j)}\right)
$$

where $\phi$ is unknown scalar parameter that quantifies spatial dependence.

### 2.4. The compound collective risk model

In the basic insurance risk model, according to [8], the number of claims and the total claim produced by a portfolio in a given time period $t=1, \ldots, T$ for some class $i$ is denoted by $\left(N_{i t}, S_{i t}\right)$ where

$$
\begin{equation*}
S_{i t}=\sum_{k=1}^{N_{i t}} W_{i t k}, \quad \text { if } \quad N_{i t}>0 \tag{2.3}
\end{equation*}
$$

and zero otherwise, where $W_{i t k}$ is the amount of the $k$ th claim at time $t$ for some class $i$.

This model is due to [12] and has the following assumptions:

- The number of claims in the interval $(t-1, t)$, denoted by $N_{i t}$, is a random variable
- The claim size $W_{i t k}, k=1,2, \ldots, n_{i t}$, is conditional on $N_{i t}=n_{i t}$. $W_{i t k}$ is positive independent and identically distributed random variables with finite mean $\mu_{i t}=\mathrm{E}\left[W_{i t k}\right]$ and variance $\sigma_{i t}^{2}=\operatorname{Var}\left(W_{k i}\right)<\infty$.
- The claim time occurs at random instants $t_{1 i} \leq t_{2 i} \leq \cdots$ and the interarrival times $T_{j i}=t_{j i}-t_{j-1, i}$ are assumed to be independent and identically exponentially distributed random variables with finite mean $\mathrm{E}\left[T_{j i}\right]=\lambda_{i}^{-1}$.

If it is assumed that the sequences $T_{j}$ and $W_{j}$ are independent from each other and the above conditions hold, then $N_{i t}$ is a homogeneous Poisson process with rate $\lambda_{i t}$. Then assuming that $W_{i t k}$ is gamma $\left(\kappa_{i t}, \theta_{i t}\right)$ distributed and that the inter-arrival times are exponentially distributed, the model is given by

$$
\begin{array}{ll}
N_{i t} \mid \lambda_{i t}, \pi_{i t} \sim \operatorname{Poisson}\left(\lambda_{i t} \pi_{i t}\right), & \lambda_{i}>0, \\
X_{i t} \mid n_{i t}, \theta_{i t} \sim \operatorname{gamma}\left(\kappa_{i t}, \theta_{i t}\right), & \theta_{i}>0,
\end{array}
$$

where $\kappa_{i t}=n_{i t} \kappa_{i}, n_{i t}$ is the observed number of claims at time $t$, for age class $i$, and $\pi_{i t}$ is the insured population at time $t$ for age class $i$. This model is often referred to as the Poisson - gamma model for compound collective risk. [8]

### 2.5. Computation using Markov chain Monte Carlo

Markov chain Monte Carlo (MCMC) is an important technique used to simulate samples from a given density, for example the density of the posterior distribution of $\theta$. The samples come in chains where each of the simulated values of $\theta$ depends on the preceding value. The basic principle is that when this chain has run sufficiently long enough it will represent the desired posterior distribution, $p(\theta \mid y)$. This distribution can be summarized by computing summary statistics from recorded values. The term Markov chain stands for a sequence of random variables $\theta^{1}, \theta^{2}, \ldots$, for which, for any $t$, the distribution of $\theta^{t}$ given all previous $\theta$ t's depends only on the most recent value, $\theta^{t-1}$. The first step of MCMC simulation is to select a starting value $\theta^{0}$ and then for each $\mathrm{t}, \theta^{t}$ is drawn from a transition distribution, $T_{t}\left(\theta^{t} \mid \theta^{t-1}\right)$ that depends on the last draw, $\theta^{t-1}$, where $T_{t}\left(\theta^{t} \mid \theta^{t-1}\right)$ must be constructed so that the Markov chain converges to the posterior distribution, $p(\theta \mid y),[9]$ and [1].

The two basic and most widely used algorithms used in MCMC are the Gibbs sampler and the Metropolis-Hastings algorithm. The Gibbs sampler was first introduced by [15] in 1984 and in 1990 [2] then showed how the method could be applied to a wide variety of Bayesian inference problems. The Metropolis-Hastings sampler was developed by [11] in 1953 and [19] in 1970. These algorithms are described in the following sections. For more informations see [17] and [1].

### 2.5.1. The Gibbs sampler

According to [9], the Gibbs sampler is a method to produce useful chain values. It requires specific knowledge about the relationship between the variables of interest. The basic idea is that if it is possible to express each of the parameters to be estimated as conditioned on all of the others, then by going through these conditional statements eventually the true joint distribution of interest is reached.

The Gibbs sampler, which is also called alternating conditional sampler, is defined in terms of subvectors of $\theta$. [1] Assume the parameter vector $\theta$ has been devided into $d$ subvectors, $\theta=\left(\theta_{1}, \ldots, \theta_{d}\right)$, then the objective is to produce a Markov chain that cycles through the subvectors of $\theta$ moving toward and then around this distribution. In each iteration $t$, a sample of each subvector is obtained by sampling from the distribution of the subvector conditioned on the latest value of the other subvector. Let

$$
p\left(\theta_{j} \mid \theta_{-j}^{t-1}, y\right)
$$

be the conditional distribution of $\theta_{j}$, given the data and the other subvectors at their current value, denoted by $\theta_{-j}^{t-1}$ where

$$
\theta_{-j}^{t-1}=\left(\theta_{1}^{t}, \ldots, \theta_{j-1}^{t}, \theta_{j+1}^{t-1}, \ldots, \theta_{d}^{t-1}\right)
$$

The Gibbs sampler proceeds by selecting a starting value for $\theta\left(\theta^{0}\right)$ and then by sampling from the $d$ conditional distribution for each $t=1 \ldots L$, where $L$ is the number of iterations. The Gibbs sampler can therefore be presented as

$$
\begin{gathered}
\theta_{1}^{t} p\left(\theta_{1}^{t} \mid \theta_{-1}^{t-1}, y\right) \\
\theta_{2}^{t} p\left(\theta_{2}^{t} \mid \theta_{-2}^{t-1}, y\right) \\
\vdots \\
\theta_{K}^{t} p\left(\theta_{K}^{t} \mid \theta_{-K}^{t-1}, y\right)
\end{gathered}
$$

Once convergence is reached, all simulation values are from the target posterior distribution and a sufficient number should then be drawn so that all areas of the
posterior are explored. During each iteration of the cycling through the $\theta$ vector, conditioning occurs on $\theta$ values that have already been sampled for that cycle otherwise the $\theta$ values are taken from the last cycle.

### 2.5.2. Metropolis-Hastings Sampler

According to [9], the full set of conditional distributions for the Gibbs sampler are often quite easy to specify from the hierarchy of the model, since conditional relationship are directly in such statements. However, the Gibbs sampler obviously does not work when the complete conditionals for the $\theta$ parameters do not have an easily obtainable form. In these cases a chain can be produced for these parameters using the Metropolis-Hasings algorithm.

In [1] it is shown that the Metropolis-Hastings algorithm for the $j$-th subvector of parameters $\theta_{j}$, in the $t$-th iteration is as follows:
i ) Sample a proposal $\theta_{j}^{*}$ from a proposal distribution with density $J_{j, t}\left(\theta_{j}^{*} \mid \theta_{j}^{t-1}\right)$.
ii ) Calculate the ratio of the densities

$$
r=\frac{p\left(\theta_{j}^{*} \mid \theta_{-j}^{t-1}, y\right) / J_{j, t}\left(\theta_{j}^{*} \mid \theta_{j}^{t-1}\right)}{p\left(\theta_{j}^{t-1} \mid \theta_{-j}^{t-1}, y\right) / J_{j, t}\left(\theta_{j}^{t-1} \mid \theta_{j}^{*}\right)}
$$

iii ) Set $\theta_{j}^{t}=\theta_{j}^{*}$ with probability $\min (r, 1)$, otherwise set $\theta_{j}^{t}=\theta_{j}^{t-1}$.
Usually it is easier to work with $r$ on the logarithmic scale in terms of numerical computation and for analytical results:

$$
\log (r)=\log p\left(\theta_{j}^{*} \mid \theta_{-j}^{t-1}, y\right)-\log J_{j, t}\left(\theta_{j}^{*} \mid \theta_{j}^{t-1}\right)-\log p\left(\theta_{j}^{t-1} \mid \theta_{-j}^{t-1}, y\right)+\log J_{j, t}\left(\theta_{j}^{t-1} \mid \theta_{j}^{*}\right)
$$

The Metropolis-Hastings step is an adaptation of a random walk, that uses an acceptance/rejection rule to converge to the specified target distribution. This acceptance rate is recommended to be $44 \%$ when $\theta_{j}$ is a scalar and $23 \%$ when $\theta_{j}$ is of higher dimension to ensure proper convergence and it is tuned by changing the variance of the proposal distribution.

### 2.6. Model comparison

For complex hierarchical models the computation of Bayes factors, according to [13], requires substantial efforts. Therefore it is helpful to consider model choice criteria which can easily be computed using the available MCMC output. Natural way to compare models is to use criterion based on trade-off between the fit of the data to the model and the corresponding complexity of the model. Proposed by [3], a Bayesian model comparison criterion based on this principle which will be described in next subsection.

### 2.6.1. Deviance Information Criterion (DIC)

The deviance information criterion, suggested by [3], for a probability model $p(y \mid \theta)$ with observed data $y=\left(y_{1}, \ldots, y_{n}\right)$ and unknown parameters $\theta$ is defined by

$$
\begin{equation*}
\mathrm{DIC}:=\mathrm{E}[D(y, \theta \mid y)]+p_{D} . \tag{2.4}
\end{equation*}
$$

which considers both model fit and model complexity where $p(y, \theta)=-2 \log (p(y \mid \theta)$. The posterior mean of $D(y, \theta), \mathrm{E}[D(y, \theta) \mid y]$ can be estimated with

$$
\hat{D}_{\text {avg }}(y)=\frac{1}{L} \sum_{l=1}^{L} D(y, \theta)
$$

and $p_{D}$ is the effective number of parameters. The effective number of parameters, $p_{D}$ measures the model complexity. $p_{D}$ is estimated with

$$
\begin{equation*}
p_{D}:=\hat{D}_{\text {avg }}(y)-D_{\hat{\theta}}(y) . \tag{2.5}
\end{equation*}
$$

The DIC criterion has been suggested as a criterion of model fit when the goal is to find a model that will be best for prediction when taking into account uncertainty due to sampling. As mentioned in [16], according to the DIC criterion the model with the smallest DIC is to be preferred. Both DIC and $p_{D}$ can easily be computed by taking the posterior mean of the deviance $\hat{D}_{\text {avg }}(y)$ and the plug-in estimate of the deviance $D_{\hat{\theta}}(y)$ by using the available MCMC output. In this project the standardizing term $f(y)$ is zero.

## 3. Data

The data set which is analyzed in this thesis, comes from the icelandic insurance company Vátryggingafélag Îslands hf. (VÍS). The data sets contain the number of claims and total claim size, categorized by year, postal code and risk category.

### 3.1. Data description

The data set contains information about car insurance premium and compensation paid from the insurance company from 1993 to 2008. The number of policy days (which is changed to policy years when using the data), $e_{i t}$, is known and not all policyholders were insured during the whole year. There are three main categories:
i ) Property loss (i. munatjón)

- Only damage to properties, not people
ii ) Bodily injury (i. líkamstjón)
- injury to people other than driver and owner of car
iii ) Drivers accident insurance (i. slysatrygging ökumanns og eiganda)
- Only injury to owner and driver of the car

The data sets contain the following variables:

- Year when claim occurs
- Risk category
- Region (postal code)
- Premiums for liability insurance
- Premium for driver accident insurance
- Number of policy days
- And for three categories i), ii) and iii)
- Estimated total compensation
- Number of claims
- Estimated unpaid compensation

Iceland is divided into 151 regions, including post office box. For convenience post office box were combined with appropriate postal codes, reducing the number of regions used to 130 . For each claim the year claim occurs, $t$, and region where policyholder is residing, $i$, is known. The original data set contains about 35.500 observations, but in this thesis only one risk category is analyzed. The data set for this category contains about 2230 observations when regions are 151 but about 2000 when regions are 130. All data have been brought to present worth but they have also been scaled for reasons of confidentiality.
In the model for claim frequency only observation with non-zero policy years are taken into account. Of course, if the number of policy years is greater than zero then account of zero for particular postal code and particular year is taken into account. In case of the model for the claim size, observations with non-zero policy years are taken into account for all occurred claims. There is a quite large amount of observations with no claim, especially in the category for divers accident insurance, see Tables 3.1, 3.2 and 3.3. They also show the maximum number of observed claims, which is most in the category for property loss.

Table 3.1: Summary of the observed claim frequencies in the data of property loss.

| Property loss |  |
| :---: | :---: |
| Number of claims | Percentage of observation |
| 0 | 43.72 |
| 1 | 17.38 |
| 2 | 9.01 |
| 3 | 4.51 |
| 4 | 3.00 |
| $\vdots$ | $\vdots$ |
| 63 | 0.05 |
| 64 | 0.05 |

In Figure 3.1 a histogram of the observed positive average claim sizes is given and in Table 3.4 is given the mean of total claim sizes per number of claims. The figure shows the average claim size is just below 100000 . From the mentioned table the total

Table 3.2: Summary of the observed claim frequencies in the data of bodily injury.

| Bodily injury |  |
| :---: | :---: |
| Number of claims | Percentage of observation |
| 0 | 77.82 |
| 1 | 9.71 |
| 2 | 5.11 |
| 3 | 2.65 |
| 4 | 1.65 |
| $\vdots$ | $\vdots$ |
| 13 | 0 |
| 14 | 0.05 |

Table 3.3: Summary of the observed claim frequencies in the data of drivers accident insurance.

| Drivers accident insurance |  |
| :---: | :---: |
| Number of claims | Percentage of observation |
| 0 | 83.93 |
| 1 | 10.82 |
| 2 | 3.15 |
| 3 | 1.45 |
| 4 | 0.50 |
| 5 | 0.05 |
| 6 | 0.05 |
| 7 | 0.05 |

Figure 3.1: Histogram of the observed positive total claim sizes per number of claims.
claim size per number of claims is 93044 . The largest average claim size observation per number of claim is 1451240 which is about $1.4 \%$ of the sum of all total claim sizes per number of claims. Based on a simple statistical test no relationship was found between number of claims and total claim sizes. Figure 3.1 and Table 3.4 are therefore describing for the data.

Table 3.4: The mean of total claim sizes per number of claims taken over all observations and over observations with $N=k, k=1,2,3,4,5,6,7,8,63,64$.

| Number of observations | Mean |
| :---: | :---: |
| All | 93044 |
| $\mathrm{~N}=1$ | 94220 |
| $\mathrm{~N}=2$ | 93970 |
| $\mathrm{~N}=3$ | 90564 |
| $\mathrm{~N}=4$ | 96060 |
| $\mathrm{~N}=5$ | 105416 |
| $\mathrm{~N}=6$ | 95580 |
| $\mathrm{~N}=7$ | 96583 |
| $\mathrm{~N}=8$ | 89150 |
| $\vdots$ | $\vdots$ |
| $\mathrm{~N}=63$ | 76020 |
| $\mathrm{~N}=64$ | 107956 |

### 3.1.1. Neighborhood matrix

In Chapter 2.3 a model describing correlation between variables based on their neighborhood structure was given. In this subsection, the matrix that describes the neighborhood structure is defined. If postal codes are neighbors, 1 connects them, otherwise there is 0 . Postal code has to have at least one neighbor and is never neighbor to it self. The neighborhood matrixes can be seen in Appendix A.
There are two kind of neighborhood structures, temporal and regional. In the neighborhood structure for time, years before and after a certain year are neighbors so each year has 2 neighbors except the first and last that only have one. The neighborhood structure for regions is defined such that regions are neighbors if they:

- share borders
- share borders with neighbors when there is strong connection
- strong connection within the capital area
- strong connection if postal codes are within the same commune

## 4. Models

Under the Poisson-gamma model for compound collective risk, see Section 2.4 the number of claims follow a Poisson distribution and are independent of the claim sizes which follow a gamma distribution. In this chapter these two models are described. The main result is expected compensation which is simply the expected claim frequency times the expected total claim size. Following there is an introduction to the Bayesian inference where prior- and posterior distributions and MCMC algorithms are described.

### 4.1. Model for claim frequency

For claim frequency, a Poisson model with spatial and temporal effects is chosen. This model is easy to use for insurance data, e.g. based on [20] and [16]. The structure of the data requires spatial and temporal effects which are easy to include to the proposed model. Considering only observations with non-zero policy years, altogether 1974 observations are obtained. The index $t$ denotes the year claim occurs and the index $i$ denotes the region where policyholder is residing. $N_{i t}$ is the number of claims in region $i$ at year $t$. The number of policy years for policyholders in region $i$ and at year $t$ is denoted by $e_{i t}$. The average number of claims per a single policy year in region $i$ at year $t$ is denoted by $\theta_{i t}$. The proposed model for number of claims is given by

$$
\begin{equation*}
N_{i t} \mid \theta_{i t} \sim \operatorname{Poisson}\left(e_{i t} * \theta_{i t}\right) \tag{4.1}
\end{equation*}
$$

or with $\theta_{i t}^{*}=\log \theta_{i t}$

$$
N_{i t} \mid \theta_{i t}^{*} \sim \operatorname{Poisson}\left(e_{i t} * \exp \left(\theta_{i t}^{*}\right)\right)
$$

where

$$
\theta_{i t}^{*}=x_{i}^{T} \beta+a_{1, t}+a_{2, i}+\varepsilon_{i t},
$$

$a_{1, t}$ and $a_{2, i}$ are temporal- and spatial factors respectively. The temporal factor is used to see if time influences the results and the spatial factor is to see if residence of policyholders influencees the results. $x_{i}$ is a vector of covariates, $\beta$ is a vector of parameters and $\varepsilon_{i t}$ is an error term which is independent over years and postal
codes,

$$
\varepsilon_{i t} \sim \mathrm{~N}\left(0, \sigma_{\varepsilon, i t}^{2}\right)
$$

where

$$
\sigma_{\varepsilon, i t}^{2}=\log \left(\frac{1}{2}+\frac{1}{2} \sqrt{1+\frac{4}{r e_{i t}}}\right)
$$

with $r$ denoting the average frequency per policy year. The calculations for $\sigma_{\varepsilon, i t}^{2}$, which changes for each policy year, can be seen in Appendix B.

To estimate the number of claims, $\theta_{i t}^{*}$, eight potential postal categories were selected and used as covariates to help explain the spatial patterns of the claims. The vector of unknown regression parameters is $\beta=\left(\beta_{1}, \ldots, \beta_{8}\right)^{\prime}$. The vector of covariates for the $i$-th observation is given by

$$
x_{i}=\left(x_{1, i}, \ldots, x_{8, i}\right)^{\prime}
$$

and includes only 0 and 1 . The main role of this matrix is to ensure that each observation is connected to the correct postal category. When deciding the postal categories, the postal codes were grouped in several ways where the groups depended on sizes of urban regions, closeness to highway, etc. The model was tested under different grouping of the postal codes. The best result was found with help of DIC. The best result consisted of eight categories which can be seen in Table 4.1.

Table 4.1: Regression covariates.

| Regression Covariates |  |  |
| :--- | :--- | :--- |
| Covariates $(x)$ | Coefficients $(\beta)$ | Postal categories |
| $x_{1}$ | $\beta_{1}$ | Reykjavík |
| $x_{2}$ | $\beta_{2}$ | Reykjavík Urban Region |
| $x_{3}$ | $\beta_{3}$ | Large Urban Region |
| $x_{4}$ | $\beta_{4}$ | Small Urban Region |
| $x_{5}$ | $\beta_{5}$ | Rural near highway |
| $x_{6}$ | $\beta_{6}$ | Rural area |
| $x_{7}$ | $\beta_{7}$ | Banks and government |
| $x_{8}$ | $\beta_{8}$ | Other |

### 4.1.1. Residual analysis

Evaluating the fit of the model to the data is an important step when building a model. Graphical residual analysis is the primary statistical tool to evaluate the fit of a model. Residuals are the difference between the measured output from the validation data set and the predicted model output. Residuals therefore represent
the portion of the validation data not explained by the model. [10] When random errors in regression models are not normally distributed it can be useful to use alternative formula to the usual residual formula, proposed by [4]. It is based on the idea to produce quantities that are close to being normal distributed, and the formula for the residuals depends on the assumed distribution. For Poisson distribution, formula for the residual is given by

$$
\begin{equation*}
e=\frac{\frac{3}{2}\left(y^{2 / 3}-\psi^{2 / 3}\right)}{\psi^{1 / 6}} \tag{4.2}
\end{equation*}
$$

where $y$ follows a Poisson distribution with mean $\psi$. Modify for the overdispersed Poisson model so that the expected value and the variance of $N_{i t}$ are conditioned on $\beta, a_{1}$ and $a_{2}$ (integrated over $e_{i t}$ ). The mean is

$$
\mathrm{E}\left(N_{i t} \mid \beta, a_{1}, a_{2}\right)=e_{i t} \exp \left(X_{i}^{T} \beta+a_{1, t}+a_{2, i}+0.5 \sigma_{\varepsilon, i t}^{2}\right)=\psi_{i t}
$$

and the variance is

$$
\operatorname{Var}\left(N_{i t} \mid \beta, a_{1}, a_{2}\right)=\psi_{i t}^{2}\left(\exp \left(\sigma_{\varepsilon, i t}^{2}\right)-1\right)+\psi_{i t}^{2} .
$$

To fit Equation (4.2) to the model for frequency of claims, according to Taylor expansion the equation becomes

$$
\begin{equation*}
e=\frac{y^{2 / 3}-\psi^{2 / 3}}{\sqrt{\sigma_{Y}^{2} \frac{4}{9} \psi^{-2 / 3}}} \tag{4.3}
\end{equation*}
$$

and by using Equations (4.2) and (4.3) together with using the transformation of $N_{i t}^{2 / 3}$ and Cramérs Theorem, [5] the residual formula for the claim frequency model, where $y$ is denoted by $N_{i t}$ is

$$
\begin{equation*}
e=\frac{N_{i t}^{2 / 3}-\exp \left(\psi_{i t}^{2 / 3}\right)}{\sqrt{\psi_{i t}^{2}\left(\exp \left(\sigma_{\varepsilon, i t}^{2}\right)-1\right)+\psi_{i t}}} * \frac{1}{\frac{2}{3}\left(\psi_{i t}\right)^{-1 / 3}} . \tag{4.4}
\end{equation*}
$$

### 4.2. Model for claim size

The proposed model for claim size is a gamma model with temporal and spatial effects and is similar to the model presented in [20] and [16]. The experience shows this kind of model is easy to use for similar projects. The structure of the data requires temporal and spatial effects. These effects are easy to include to the proposed
model. In this model only observations with positive number of claims and non-zero policy years are taken into account, altogether 1108 observations are obtained. $S_{i t}$ is the total size of claims in region $i$ and year $t$. The average size of each claim is denoted by $\mu_{i t}$ and $\sigma_{i t}$ denotes the standard deviation of each claim.
The original idea for this model is similar to the model for claim frequency. The $\log$-mean parameter $\mu^{*}$ is similar to $\theta^{*}$ and the factors $d_{1}$ and $d_{2}$ are similar to $a_{1}$ and $a_{2}$, i.e. temporal and spatial effects respectively. The log-mean is modeled as $X_{i}^{T} \eta+d_{1, t}+d_{2, i}$ but in the final analysis $d_{2}$ was cut out from the model. Nonetheless $d_{2}$ will be included in this chapter, but will be discussed further in Chapter 5.

The covariate vector is the same as for the model for claim frequency, $x_{i}=\left(x_{i 1}, \ldots, x_{i 8}\right)^{\prime}$, only containing 0 and 1 . The vector of unknown regression parameters is $\eta=$ $\left(\eta_{1}, \ldots, \eta_{8}\right)^{\prime}$.

$$
\begin{equation*}
S_{i t} \mid N_{i t} \sim \operatorname{gamma}\left(N_{i t} \mu_{i t}, N_{i t} \sigma_{i t}^{2}\right) \tag{4.5}
\end{equation*}
$$

where the gamma distribution is parameterized by its mean and variance, and

$$
\begin{gathered}
\mu_{i t}=\exp \left(x_{i}^{T} \eta+d_{1, t}+d_{2, i}\right) \\
\sigma_{i t}^{2}=\frac{\mu_{i t}^{2}}{\alpha} \quad \text { where } \alpha \text { is an unknown parameter } \\
S_{i t}=\sum_{k=1}^{N_{i t}} W_{i t k}, \quad W_{k, i t} \sim \operatorname{gamma}\left(\mu_{i t}, \sigma_{i t}^{2}\right)
\end{gathered}
$$

where $W_{i t k}$ is the cost for individual claim, which is unknown.
Like for claim frequency, model validation with graphical analyzation of the residuals is made for the claim sizes. Also proposed by [4], a model for residuals in case of gamma distribution with mean $\mu$

$$
\begin{equation*}
e=\frac{3\left(y^{1 / 3}-\mu^{1 / 3}\right)}{2 \mu^{1 / 3}} . \tag{4.6}
\end{equation*}
$$

The formula in 4.6 needs to be corrected by including the square root of $\alpha$. That is by letting

$$
\begin{equation*}
e=\frac{3 \sqrt{\alpha}\left(y^{1 / 3}-\mu^{1 / 3}\right)}{2 \mu^{1 / 3}}, \tag{4.7}
\end{equation*}
$$

the variance of $e$ becomes approximately 1 . In case of the model for $S_{i t}$

$$
\begin{equation*}
e=\frac{3 \sqrt{\alpha N_{i t}}\left(S_{i t}^{1 / 3}-N_{i t}^{1 / 3} \mu_{i t}^{1 / 3}\right)}{2 N_{i t}^{1 / 3} \mu_{i t}^{1 / 3}} \tag{4.8}
\end{equation*}
$$

with $\alpha_{i t}$ and $\beta_{i t}$ are such that

$$
\begin{gathered}
\alpha_{i t}=\alpha \cdot N_{i t}, \\
\beta_{i t}=\alpha \cdot \exp (-\mu)
\end{gathered}
$$

where $\alpha_{i t}$ and $\beta_{i t}$ are the usual parameters of the gamma distribution and

$$
\mu_{i t}=\frac{\alpha_{i t}}{\beta_{i t}} .
$$

### 4.3. Expected compensation

The main aim of the research in this thesis is to find out the expected total compensation cost the insurance company has to pay. This cost will depend on models for claim frequency and claim size, and is examined for each postal code where policyholder is residing. The expected value is the expected total cost $\left(S_{i t}\right)$ per number of policy years $\left(e_{i t}\right)$ and the final result is a combination of the two main models mentioned earlier in this chapter. Despite of this combination, the uncertainty does not increase since each part is calculated separately.

$$
\begin{align*}
E\left(\frac{S_{i t}}{e_{i t}}\right) & =\frac{1}{e_{i t}} E\left(S_{i t}\right) \\
& =\frac{1}{e_{i t}} E\left(\sum_{k=1}^{N_{i t}} W_{k, i t}\right) \\
& =\frac{1}{e_{i t}} E\left(E\left(\sum_{k=1}^{N_{i t}} W_{k, i t} \mid N_{i t}\right)\right) \\
& =\frac{1}{e_{i t}} E\left(\sum_{k=1}^{N_{i t}} E\left(W_{k, i t}\right) \mid N_{i t}\right) \\
& =\frac{1}{e_{i t}} E\left(N_{i t} E\left(W_{1, i t}\right)\right)  \tag{4.9}\\
& =\frac{1}{e_{i t}} E\left(N_{i t}\right) E\left(W_{1, i t}\right) \\
& =\frac{1}{e_{i t}} E\left(E\left(N_{i t} \mid \theta_{i t}^{*}\right)\right) \mu_{i t} \\
& =\frac{1}{e_{i t}} E\left(e_{i t} \theta_{i t}^{*}\right) \exp \left(x_{i}^{T} \eta+d_{1, t}+d_{2, i}\right) \\
& =\exp \left(x_{i}^{T} \beta+a_{1, t}+a_{2, i}+\frac{1}{2} \sigma_{\varepsilon}^{2}\right) \exp \left(x_{i}^{T} \eta+d_{1, t}+d_{2, i}\right)
\end{align*}
$$

where $\exp \left(x_{i}^{T} \beta+a_{1, t}+a_{2, i}+\frac{1}{2} \sigma_{\varepsilon}^{2}\right)$ is the Poisson part of the model and $\exp \left(x_{i}^{T} \eta+d_{1}, t+\right.$ $d_{2, i}$ ) is the gamma part of the model, see Equations (4.2) and (4.6), respectively.

### 4.4. Bayesian inference

### 4.4.1. Prior distributions

An important part of Bayesian inference is the selection of appropriate prior distributions for the unknown parameters. For the model for claim frequency the prior distributions for the parameters mentioned in Section 4.1 are assumed to be as follows:

$$
\begin{align*}
\beta & \sim N\left(\mu_{\beta}, \sigma_{\beta}^{2} I\right) \\
a_{1} & \sim N\left(\overline{0}, \tau_{1}^{2}\left(I-\phi_{1} C_{1}\right)^{-1} M_{1}\right) \\
a_{2} & \sim N\left(\overline{0}, \tau_{1}^{2}\left(I-\phi_{2} C_{2}\right)^{-2} M_{2}\right)  \tag{4.10}\\
\varepsilon_{i t} & \sim N\left(\overline{0}, \sigma_{\varepsilon, i t}^{2} I\right)
\end{align*}
$$

where $N(\cdot, \cdot)$ indicates the normal distribution. $\mu_{\beta}$ and $\sigma_{\beta}$ are selection based preanalysis of data. $\beta$ is estimated with Maximum likelihood estimation in a model with $\theta^{*}=x_{i} \beta . \mu_{\beta}$ is the mean of $\hat{\beta}$ and $\sigma_{\beta}^{2}$ is $C$ times the variance of $\hat{\beta}$, where $C$ is a multiplication factor for the variance decided with experiments on the model with default value equal to 4 in the model for claim frequency and equal to 0.5 for the model for claim size. This is done to get the estimation of $\beta$ stable.

The hyperparameters are $\sigma_{\varepsilon}^{2}, \tau_{1}^{2}, \tau_{2}^{2}, \phi_{1}$ and $\phi_{2}$. A non-informative prior distribution - scaled inverse- $\chi^{2}$ is chosen for $\sigma_{\varepsilon, i t}^{2}, \tau_{1}^{2}$ and $\tau_{2}^{2}$. For $\phi_{1}$ and $\phi_{2}$ beta distribution is chosen to ensure strong correlation.

$$
\begin{array}{ll}
\sigma_{\varepsilon}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{\varepsilon}, S_{\varepsilon}^{2}\right) & \nu_{\varepsilon}=10^{-6},
\end{array} \begin{aligned}
& S_{\varepsilon}^{2}=1 \\
& \tau_{1}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{\tau 1}, S_{\tau 1}^{2}\right) \\
& \nu_{\tau 1}=10^{-6},
\end{aligned} \begin{aligned}
& S_{\tau 1}^{2}=1  \tag{4.11}\\
& \tau_{2}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{\tau 2}, S_{\tau 2}^{2}\right) \\
& \nu_{\tau 2}=10^{-6},
\end{aligned} \begin{array}{ll}
S_{\tau 2}^{2}=1 \\
\phi_{1} \sim \operatorname{beta}\left(\alpha_{\phi 1}, \beta_{\phi 1}\right) & \alpha_{\phi 1}=100, \\
\beta_{\phi 1}=0.5 \\
\phi_{2} \sim \operatorname{beta}\left(\alpha_{\phi 2}, \beta_{\phi 2}\right) & \alpha_{\phi 2}=100, \\
\beta_{\phi 2}=0.5
\end{array}
$$

Similar for claim size, the prior distributions are as follows:

$$
\begin{align*}
\eta & \sim N\left(\mu_{\eta}, \sigma_{\eta}^{2} I\right) \\
d_{1} & \sim N\left(\overline{0}, \kappa_{1}^{2}\left(I-\zeta_{1} C_{1}\right)^{-1} M_{1}\right) \\
d_{2} & \sim N\left(\overline{0}, \kappa_{2}^{2}\left(I-\zeta_{2} C_{2}\right)^{-1} M_{2}\right)  \tag{4.12}\\
\alpha & \sim \operatorname{gamma}\left(\alpha_{0}, \beta_{0}\right)
\end{align*}
$$

where $N(\cdot, \cdot)$ indicates the normal distribution. The parameters in the gamma model are estimated similar to the parameters in the model for claim frequency. $\mu_{\eta}$ and $\sigma_{\eta}$ are selection based pre-analysis of data. $\eta$ is estimated with Maximum likelihood estimation in a model $x_{i} \eta . \mu_{\eta}$ is the mean of $\hat{\eta}$. For $\alpha$ gamma distribution is chosen with parameters $\alpha_{0}=1$ and $\beta_{0}=1$. The hyperparameters are $\sigma_{r}^{2}, \kappa_{1}^{2}, \kappa_{2}^{2}, \zeta_{1}$ and $\zeta_{2}$. A non-informative prior distribution - scaled inverse- $\chi^{2}$ is chosen for $\sigma_{r}^{2}, \kappa_{1}^{2}$ and $\kappa_{2}^{2}$. For $\zeta_{1}$ and $\zeta_{2}$ beta distribution is chosen to ensure strong correlation.

$$
\begin{align*}
& \sigma_{r}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{r}, S_{r}^{2}\right) \quad \nu_{r}=10^{-6}, \quad S_{r}^{2}=1 \\
& \kappa_{1}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{\kappa 1}, S_{\kappa 1}^{2}\right) \quad \nu_{\kappa 1}=10^{-6}, \quad S_{\kappa 1}^{2}=1 \\
& \kappa_{2}^{2} \sim \operatorname{Inv}-\chi^{2}\left(\nu_{\kappa 2}, S_{\kappa 2}^{2}\right) \quad \nu_{\kappa 2}=10^{-6}, \quad S_{\kappa 2}^{2}=1  \tag{4.13}\\
& \zeta_{1} \sim \operatorname{beta}\left(\alpha_{\zeta 1}, \beta_{\zeta 1}\right) \quad \alpha_{\zeta 1}=100, \quad \beta_{\zeta 1}=0.5 \\
& \zeta_{2} \sim \operatorname{beta}\left(\alpha_{\zeta 2}, \beta_{\zeta 2}\right) \quad \alpha_{\zeta 2}=100, \quad \beta_{\zeta 2}=0.5
\end{align*}
$$

### 4.4.2. Posterior distributions

The posterior distributions of the parameters, given the observed claim numbers and claim sizes, describe the statistical uncertainty and is the tool for inference in a Bayesian analysis. Analytically, the posterior density is the product of the prior density and the likelihood. The posterior distribution for the model of claim frequency is

$$
\begin{align*}
p\left(\theta_{i t}^{*}, a_{1}, a_{2}, \beta, \sigma_{\varepsilon, i t}^{2}, \tau_{1}^{2}, \tau_{2}^{2}, \phi_{1}, \phi_{2} \mid N_{i t}\right) \propto & p\left(N_{i t} \mid \theta_{i t}^{*}\right) \\
& \times p\left(\theta_{i t}^{*} \mid a_{1}, a_{1}, \beta, \sigma_{\varepsilon, i t}^{2}\right) \\
& \times p\left(a_{1} \mid \tau_{1}^{2}, \phi_{1}\right) \times p\left(a_{2} \mid \tau_{2}^{2}, \phi_{2}\right) \\
& \times p(\beta) p\left(\sigma_{\varepsilon, i t}^{2}\right) p\left(\tau_{1}^{2}\right) p\left(\tau_{2}^{2}\right) p\left(\phi_{1}\right) p\left(\phi_{2}\right) \\
\propto & \prod_{i=1}^{J} \prod_{t=1}^{T} \operatorname{Poisson}\left(N_{i t} \mid e_{i t} \theta_{i t}^{*}\right) \\
& \times \prod_{i=1}^{J} \prod_{t=1}^{T} \mathrm{~N}\left(\theta^{*} \mid x_{i}^{T} \beta+a_{1, t}+a_{2, i}, \sigma_{\varepsilon, i t}^{2}\right) \\
& \times \mathrm{N}\left(a_{1} \mid \underline{0}, \tau_{1}^{2}\left(I-\phi_{1} C_{1}\right)^{-1} M_{1}\right) \\
& \times \mathrm{N}\left(a_{2} \mid \underline{0}, \tau_{2}^{2}\left(I-\phi_{2} C_{2}\right)^{-1} M_{2}\right) \\
& \times \mathrm{N}\left(\beta \mid \mu_{\beta}, \sigma_{\beta}^{2} I\right) \operatorname{Inv}-\chi^{2}\left(\sigma_{\varepsilon}^{2} \mid \nu_{\varepsilon}, S_{\varepsilon}^{2}\right) \\
& \operatorname{Inv}-\chi^{2}\left(\tau_{1}^{2} \mid \nu_{\tau 1}, S_{\tau 1}^{2}\right) \operatorname{Inv}-\chi^{2}\left(\tau_{2}^{2} \mid \nu_{\tau 2}, S_{\tau 2}^{2}\right) \\
& \times \operatorname{beta}\left(\phi_{1} \mid \alpha_{\phi 1}, \beta_{\phi 1}\right) \operatorname{beta}\left(\phi_{2} \mid \alpha_{\phi 2}, \beta_{\phi 2}\right) \tag{4.14}
\end{align*}
$$

The posterior distribution for the claim sizes is

$$
\begin{align*}
p\left(d_{1}, d_{2}, \eta, \kappa_{1}^{2}, \kappa_{2}^{2}, \zeta_{1}, \zeta_{2}, \alpha \mid S_{i t}\right) \propto & p\left(S_{i t} \mid \eta, d_{1}, d_{2}, \alpha, N_{i t}\right) \\
& \times p\left(d_{1} \mid \kappa_{1}^{2}, \zeta_{1}\right) \times p\left(d_{2} \mid \kappa_{2}^{2}, \zeta_{2}\right) \\
& \times p(\eta) p(\alpha) p\left(\zeta_{1}\right) p\left(\zeta_{2}\right) \\
\propto & \prod_{i=1}^{J} \prod_{t=1}^{T} \operatorname{gamma}\left[S_{i t} \mid N_{i t} \exp \left(\lambda_{i t}\right), \frac{N_{i t}}{\alpha} \exp \left(2 \lambda_{i t}\right)\right] \\
& \times \mathrm{N}\left(d_{1} \mid \underline{0}, \kappa_{1}^{2}\left(I-\zeta_{1} C_{1}\right)^{-1} M_{1}\right) \\
& \times \mathrm{N}\left(d_{2} \mid \underline{0}, \kappa_{2}^{2}\left(I-\zeta_{2} C_{2}\right)^{-1} M_{2}\right) \\
& \times \mathrm{N}\left(\eta \mid \mu_{\eta}, \sigma_{\eta}^{2} I\right) \times \operatorname{gamma}\left(\alpha_{0}, \beta_{0}\right) \\
& \times \operatorname{Inv}-\chi^{2}\left(\kappa_{1}^{2} \mid \nu_{\kappa 1}, S_{\kappa 1}^{2}\right) \operatorname{Inv}-\chi^{2}\left(\kappa_{2}^{2} \mid \nu_{\kappa 2}, S_{\kappa 2}^{2}\right) \\
& \times \operatorname{beta}\left(\zeta_{1} \mid \alpha_{\zeta 1}, \beta_{\zeta 1}\right) \operatorname{beta}\left(\zeta_{2} \mid \alpha_{\zeta 2}, \beta_{\zeta 2}\right) \tag{4.15}
\end{align*}
$$

When finding the posterior distribution for the model for claim sizes first it is good to parameterize the model with the mean and variance. In Chapter 2 are the basic equations for the gamma model expressed, see Equations (2.1), (2.1) and (2.2). The usual parametrization is as follows:

$$
\begin{gathered}
\frac{\alpha}{\beta}=\mu \\
\frac{\alpha}{\beta^{2}}=\sigma^{2}=\frac{1}{\alpha} \frac{\alpha^{2}}{\beta^{2}}=\frac{1}{\alpha} \mu^{2} .
\end{gathered}
$$

This gives

$$
\begin{gather*}
\alpha=\frac{\mu^{2}}{\sigma^{2}} \\
\text { and } \\
\beta=\frac{\alpha}{\mu}=\frac{1}{\mu} \frac{\mu^{2}}{\sigma^{2}}=\frac{\mu}{\sigma^{2}} . \tag{4.16}
\end{gather*}
$$

Then the parametrization for this model is

$$
\begin{align*}
\lambda_{i t} & =x_{i}^{T} \eta+d_{1, t}+d_{2, i} \\
\mu_{i t} & =N_{i t} \exp \left(\lambda_{i t}\right) \\
\sigma_{i t}^{2} & =\frac{1}{\alpha} N_{i t} \exp \left(2 \lambda_{i t}\right)  \tag{4.17}\\
\alpha_{i t} & =\frac{N_{i t}^{2} \exp \left(2 \lambda_{i t}\right)}{\frac{1}{\alpha} N_{i t} \exp \left(2 \lambda_{i t}\right)}=\alpha N_{i t}, \\
\beta_{i t} & =\frac{N_{i t} \exp \left(\lambda_{i t}\right)}{\frac{1}{\alpha} N_{i t} \exp \left(2 \lambda_{i t}\right)}=\alpha \exp \left(-\lambda_{i t}\right) .
\end{align*}
$$

This parametrization is used in the calculations for the conditional distributions of the claim size model in Subsection 4.4.3.

### 4.4.3. MCMC

As mentioned in Section 2.5, Gibbs sampler is one kind of MCMC simulations. Gibbs sampler is used to simulate samples from the posterior distributions. It is sufficient to have 4 chains. Starting values are determined with experiments and then the MCMC algorithms are run for 15000 iterations. A burn-in of 4500-5000 iterations is found to be sufficient after experiments on the MCMC trace plots.

Sampling from the posterior distribution by using the Gibbs sampler gives the conditional distribution for all parameters. In Appendix C, conditional distributions for all parameters are expressed.

## 5. Results

In this chapter the main results of an analysis based on the derived methods are given. First, results on the expected claim frequency per policy year, expected total claim size per policy year and the expected compensation cost per policy year, both for the postal categories and for each postal code. Following, there are results from the claim frequency model and results from the claim size model. Finally, results on the expected compensation cost, which is based on these two models, is introduced. In Chapter 3, three categories for mandatory liability insurances for vehicles are mentioned. Here, only results for one category, property loss, will be listed out, both for claim frequency and claim size. Also, there are three postal codes that have no neighbors. According to the postal categories they belong to banks and government (postal codes 150 and 155) and other (postal code 999). These postal codes are not included in figures in this chapter and grouped separately in the postal categories.

### 5.1. Main results

In Chapter 4, eight different postal categories were introduced. Table 5.1 shows for these postal categories their expected claim frequency per number of policy years, their expected claim size per number of policy years and their expected compensation per number of policy years. This table shows the number of claims is highest in Reykjavík, urban regions around Reykjavík and Large urban regions but lowest in the rural areas near highway and the same is for expected compensation. In Appendix D, Tables D.1-D. 3 are similar to Table 5.1, but these tables also give upper and lower bounds for $95 \%$ posterior interval. For example for claim frequency and category 1 the lower $95 \%$ interval is 0.061 which is larger than e.g. category 4 which has the upper $95 \%$ interval as 0.056 and therefore shows there is significant difference between these categories. It is interesting that the cost is higher in rural area than rural near highway. These two postal categories were examined further in terms of what postal codes were included. Based on this examination there was no reason to make changes. Claim size on the other hand is very similar between postal categories.

Table 5.1: Expected claim frequency, total claim size and compensation per policy year for the eight postal categories.

| Numeric <br> code | Region | Claim <br> frequency | Claim <br> size | Expected <br> compensation |
| :---: | :---: | :---: | :---: | :---: |
| 1 | Reykjavík | 0.0743 | 82290 | 6113 |
| 2 | Reykjavík urban region | 0.0663 | 82001 | 5440 |
| 3 | Large urban region | 0.0644 | 86078 | 5539 |
| 4 | Small urban region | 0.0513 | 88740 | 4551 |
| 5 | Rural near highway | 0.0460 | 86080 | 3956 |
| 6 | Rural area | 0.0505 | 86729 | 4377 |
| 7 | Banks and government | 0.1101 | 93742 | 10321 |
| 8 | Other | 0.0751 | 88912 | 6674 |

Table 5.2 is similar to Table 5.1. However, instead of postal categories all postal codes are expressed. The results are in line with results in Table 5.1, with the highest frequency and expected compensation in the capital area and lowest in the countryside. Size of claims are very similar between postal categories and are the same for postal codes within the same postal category. In Appendix D, Tables D. 4 - D. 6 are similar to Table 5.2 but these tables also give upper and lower bounds for $95 \%$ posterior intervals. For claim frequency the average lower bound multiplication factor is 0.6583 (about $34 \%$ is subtracted from the posterior mean) and the upper bound multiplication factor is 1.4593 (about $46 \%$ is added to the posterior mean). For claim sizes the lower bound multiplication factor is 0.8493 (about $15 \%$ is subtracted from the posterior mean) and the upper bound multiplication factor is 1.1899 (about $19 \%$ is added to the posterior mean). For expected value the lower bound multiplication factor is 0.6341 (about $37 \%$ is subtracted from the posterior mean) and upper bound multiplication factor is 1.5083 (about $51 \%$ is added to the posterior mean).

For better explanation, the expected compensation cost is shown graphically for all postal codes in Figure 5.1. There is a good overview for the numbers in the second last column in Table 5.2. Since the expected claim frequency reflects the expected compensation, and the expected total claim sizes are similar for all postal codes, it was decided only to show the expected compensation graphically, like in Figure 5.1. As can be seen, a few postal codes outside of the capital area have a large amount of expected compensation, even though it is a small region (for example postal codes 233,345 and 611). This is explained by unusual amount of occurred claims during some years when compared to other years for that postal code (where the amount of policyholders is still the same) and the frequency of claims in nearby postal codes.

Figure 5.1: Expected compensation cost for each postal code. Green dot present expected compensation less than 4000, yellow dot present postal codes where expected compensation are between 4000 and 5500. Red dot present expected compensation between 5500 and 7000 and finally the blue one present expected compensation higher than 7000.

Table 5.2: Table with posterior mean for expected claim frequency per policy year (Poisson), expected total claim size per policy year (gamma) and expected compensation cost per policy year.

### 5.2. Claim frequency

The analysis of claim frequency is based on the Bayesian approach and MCMC. Statistical results are found by using simulated samples to compute the posterior mean, standard deviation and percentiles for all parameters. MCMC trace plots for all parameters are examined and residuals are analyzed. Then model comparison was made with DIC calculations, introduced in Chapter 2. The model was tested with different coefficient $C$, different postal category matrix and finally models with and without spatial and temporal factors were compared, and the best model chosen. The trace plots for all model parameters are presented in Figures 5.2-5.5. There are 16 different $a_{1}$ parameters depending on each year. Similarly, there are 130 different postal codes and therefore 130 different $a_{2}$ parameters, 8 different regression parameters $\beta$ according to postal categories and $1974 \theta^{*}$ parameters depending on the whole data for claim frequency with some number of policy years. For each of $a_{1}, a_{2}, \beta$ and $\theta^{*}$, one element is picked randomly to show its trace plot. These plots are used to see if all parameters are stable, and Figures 5.2-5.5 show stable parameters. It is not necessary to have equal axis for all parameters since there is no need to compare the plots between parameters.

Residual plots based on residual analysis is shown in Figure 5.6. Formula for the residuals is presented in Chapter 4, see Equation (4.2). The figure shows that the residuals for claim frequency behave as expected with the exception that the variance appears to be a little bit higher when expected value is between zero and five constant as opposed to being constant. The average is around zero as expected.

Next step is to compare the for-mentioned model for claim frequency using DIC, the lower DIC value and effective parameters $\left(p_{D}\right)$ give, the better results can be obtained. First, the model was run with different multiplication factor $C$ (introduced in Chapter 4).

Table 5.3 shows, from $C=4$, the value on effective parameter increases with lower value on $C$. It also increases when $C=5$. The model gives good results when $C=4$ in terms of $p_{D}$ and DIC is low. Based on these results, a decision is made

Figure 5.2: MCMC trace plots for parameters $a_{1,5}$ and $a_{2,72}$ for 15000 iterations, burn-in of 4500 and 4 chains.

Figure 5.3: MCMC trace plots for parameters $\beta_{4}$ and $\theta_{135}^{*}$ for 15000 iterations, burn-in of 4500 and 4 chains.
to set the value of $C$ equal to 4 . The next step is to test the model with different postal category matrices, see results in Table 5.4. First there is only 1 category where all postal codes are in one and the same category. Next there are 6 categories which is similar to the categories introduced in Table 4.1, except postal codes in Reykjavík and Reykjavík urban region are combined and rural areas and rural areas near highway were combined. Then the postal category matrix with eight categories is tried out. Finally the postal categories are 9 , which is similar to the 8 -th category matrix but there are two categories with small urban region, one close to the highway

Figure 5.4: MCMC trace plots for parameters $\tau_{1}^{2}$ and $\tau_{2}^{2}$ for 15000 iterations, burn-in of 4500 and 4 chains.

Figure 5.5: MCMC trace plots for parameters $\phi_{1}$ and $\phi_{2}$ for 15000 iterations, burn-in of 4500 and 4 chains.
and the other one not.
Table 5.4 shows the lowest value of both DIC and effective number of parameters is when there are 8 postal categories, which is used in the following calculations. Finally the model is tested with and without the temporal effects and the spatial effects. First, only $a_{1}$ is taken out of the model and $a_{2}$ is included. Next it is the opposite, $a_{1}$ in and $a_{2}$ out. Following both parameters are taken out of the model and finally both are included in the model (which should give the same results as

Table 5.3: DIC calculations for Poisson model with different coefficient $C . p_{D}$ is the effective number of parameters.

| DIC calculations |  |  |
| :---: | :---: | :---: |
| Coefficient | DIC | $p_{D}$ |
| $C=0.5$ | 5387.7 | 589.59 |
| $C=1$ | 5381.0 | 587.48 |
| $C=1.5$ | 5378.1 | 586.77 |
| $C=2$ | 5377.5 | 586.58 |
| $C=3$ | 5376.1 | 586.08 |
| $C=4$ | 5375.4 | 585.78 |
| $C=5$ | 5375.6 | 586.14 |

Table 5.4: DIC calculations for Poisson model with different postal category matrix. $p_{D}$ is the effective number of parameters.

| DIC calculations |  |  |
| :---: | :---: | :---: |
| Postal category matrix | DIC | $p_{D}$ |
| X:1 | 5401.3 | 599.43 |
| X:6 | 5377.6 | 588.42 |
| X:8 | 5375.4 | 585.78 |
| X:9 | 5376.9 | 586.04 |

Figure 5.6: Residual plot with residuals of the Poisson model on the $y$-axis versus $\exp \left(\mu+0.5 * \sigma_{i t}^{2}\right)$ where $\mu=X \beta+a_{1, t}+a_{2, i}+\log \left(e_{i t}\right)$ on the $x$-axis.

Table 5.4 with 8 postal categories.

Table 5.5: DIC calculations for Poisson model with and without spatial and temporal effects. $p_{D}$ is the effective number of parameters.

| DIC calculations |  |  |
| :---: | :---: | :---: |
| Factors | DIC | $p_{D}$ |
| $a_{1}$ out | 5379.0 | 585.17 |
| $a_{2}$ out | 5403.1 | 579.32 |
| $a_{1}$ and $a_{2}$ out | 5410.7 | 579.23 |
| $a_{1}$ and $a_{2}$ included | 5375.6 | 585.72 |

Table 5.5 shows the model is better when $a_{2}$ is included. DIC is lower when $a_{1}$ and $a_{2}$ are both included, but for effective parameters the value is a little bit lower when $a_{1}$ is out. According to Figure 5.7 the time factor, $\exp \left(a_{1}\right)$, could be insignificant since the medium line (around 1) does not cut the confidence interval. But Table 5.5 shows the inclusion of $a_{1}$ at least dose not make the fit worse. There is a possibility of years with more claims and from Figure 5.7 can be seen that one year, in 1999, number of claims are notably topping, even though the data have been brought to present worth. Also, the lower confidence interval is very close to the medium line so it has been decided for the claim frequency model to include both $a_{1}$ and $a_{2}$. Then the final model has multiplication factor $C=4,8$ postal categories and both $a_{1}$ and $a_{2}$ included in the model. According to the insurance company, one of a possible reasons why years 1999 and 2000 were heavy in claims is that this was a time of economic growth in the society, which leads to increasing number of cars and more
stressful traffic. After the year 2000 the claim frequency gets lower again which can be because of regression after the growth, discussions about traffic accidents along with consequences of higher premiums, which raised a lot around the year 2000.

Figure 5.7: The temporal factor $a_{1}$ as a function of time. This figure shows the exponential value of the factor, i.e. $\exp \left(a_{1}\right)$.

Following, the results from the Poisson model are analyzed graphically where postal codes are on the x axis and frequency is on the y axis.

Figure 5.8: Expected claim frequency based on the Poisson model and raw frequency estimates for all postal codes along with $95 \%$ posterior interval. The postal codes are on the $x$-axis and the claim frequency are on the $y$-axis.

Figure 5.8 shows there is areal trend in the data. It shows the frequency of claims depends on where policyholder is residing. Figures E.1-E. 10 in Appendix E give
more accurate results where only a part of the postal codes are on each figure. The frequency of claims is highest in the capital area, mostly postal codes that belong to the postal categories Reykjavík and Reykjavík urban region. A few postal codes belonging to the postal category large urban region have similar claim frequency or between 0.06 and 0.08 claims per policy year. Most postal codes in the postal categories small urban regions and rural areas have claim frequency between 0.04 and 0.06 claims per policy year. As can be seen in Figure 5.8, the posterior interval for some postal codes is large. These postal codes are mainly 233,345 and 611 . The reason for this is the same as explained for Figure 5.1, i.e. these postal codes have small amount of claims. During some years, unusual amount of claims occurred when compared to other years for that postal code (the amount of policyholders is still similar) and the frequency of claims in nearby postal codes.

### 5.3. Claim size

The model for claim size was handled and applied similar by the model for claim frequency. Mean, standard deviation and percentiles were calculated for all parameters. MCMC trace- and residual plots analyzed and model comparison with DIC calculations. Trace plots are shown in Figures 5.9-5.11. These plots are used to see if model parameters are stable, and from the figures can be seen all parameters are stable. Like for $a_{1}$ and $a_{2}$, there are 16 different $d_{1}$ parameters and 130 different parameters for $d_{2}$. Also 8 different regression parameters $\eta$ exist according to postal categories. For each of the parameter vectors $d_{1}, d_{2}$ and $\eta$, one element is picked randomly to show on the trace plot.

Following, residual plots based on residual analysis are examined. Calculations for the residuals are according to Equation (4.8) introduced in Chapter 4.

Figure 5.12 show that the residuals for the claim size behave like expected. The average is around zero, points equally distributed for different values of the expected claim size which is on the x -axis and no trend in the plot. The variance appears to be constant as a function of expected claim size. Continuing, model comparison was done for changes in the model. Like before, the lower value DIC and effective parameters give, the better results are obtained. Similar to claim frequency, the model is run for different coefficient $C$, changed postal category matrix and with and without $d_{1}$ and $d_{2}$.

According to Table 5.6, the value for DIC is very similar independent of coefficient $C$. But it is obvious the number of effective parameters decreases with lower value on $C$. Since different values of $C$ only moderately influence the number of effective parameter, $p_{D}$ in the model, the best result is obtained with $C=0.5$, which is used

Figure 5.9: MCMC trace plots for parameters $d_{1,11}$ and $d_{2,72}$ for 15000 iterations, burn-in of 5000 and 4 chains.

Figure 5.10: MCMC trace plots for parameters $\alpha$ and $\eta_{3}$ for 15000 iterations, burnin of 5000 and 4 chains.
in the following calculations. Next step is to compare the model with different postal category matrix. The matrix was changed like the model for claim frequency was tested, using 6, 8 and 9 categories, see Subsection 5.2.

The value of DIC and effective number of parameters is very similar independent of size of postal category matrix. The lowest DIC is obtained when there are 9 categories but then the highest number of $p_{D}$ follows. The lowest $p_{D}$ is when there are 6 categories but then the highest value of DIC occurs. When there are 8 categories

Table 5.6: DIC calculations for gamma model with different coefficient C. $p_{D}$ is the effective number of parameters.

| DIC calculations |  |  |
| :---: | :---: | :---: |
| Coefficient | DIC | $p_{D}$ |
| $C=0.5$ | 31650 | 15.55 |
| $C=1$ | 31651 | 16.39 |
| $C=1.5$ | 31651 | 16.85 |
| $C=2$ | 31651 | 17.45 |
| $C=3$ | 31651 | 17.52 |
| $C=4$ | 31651 | 17.73 |

Table 5.7: DIC calculations for the gamma model with different postal category matrix. $p_{D}$ is the effective number of parameters.

| DIC calculations |  |  |
| :---: | :---: | :---: |
| Postal category matrix | DIC | $p_{D}$ |
| X:6 | 31651 | 14.50 |
| X:8 | 31650 | 15.63 |
| X:9 | 31649 | 16.13 |

Figure 5.11: MCMC trace plots for parameters $\kappa_{1}^{2}$ and $\kappa_{2}^{2}$ for 15000 iterations, burnin of 5000 and 4 chains.

Figure 5.12: Residual plot with residuals of the gamma model on the $y$-axis versus $N_{i t} \exp \left(\mu^{*}\right)$ where $\mu^{*}=X \eta+d_{1, t}$.
it is in the middle. Since these different categories give very similar results, the model with 8 postal categories is chosen for convenience, because it is the same postal category matrix as used for the claim frequency model and is this result used in following calculations. Finally the model is compared with and without spatial factors.

Table 5.8 shows the model is better when $d_{1}$ is included in the model. Results are similar with only $d_{1}$ in the model and both $d_{1}$ and $d_{2}$, whether DIC or the effective

Table 5.8: DIC calculations for gamma model with and without spatial and temporal effects. $p_{D}$ is the effective number of parameters.

| DIC |  |  |
| :---: | :---: | :---: |
| Factors | DIC | $p_{D}$ |
| $d_{1}$ out | 31677 | 34.14 |
| $d_{2}$ out | 31650 | 15.63 |
| $d_{1}$ and $d_{2}$ out | 31685 | 6.41 |
| $d_{1}$ and $d_{2}$ included | 31644 | 34.16 |

number of parameters are examined. DIC is though a little bit lower when both factors are included, but after looking more thoroughly at the regional factor $d_{2}$, see Figure 5.14, it shows this factor has small influences on the results so it was taken out of the model. But there is always some regional effect because of the postal categories, i.e. $d_{2}$ has almost no effect but $X \eta$ has a small effect. According to both Table 5.8 and Figure 5.13 temporal factor has great influences on the results. The figure shows that in 1999 more claims occurs which is in context with information from VÍS that say 1999 was very high in claims. Similar to the claim frequency, the total claim size increases in 1999 and 2000, among others because of economic growth in the society. In times like that, more expensive cars are on the streets and repair cost also raises which leads to higher claims for the insurance company to pay. Also, in 1999 the laws of Tort Damages Act were changed which increased the size of claims, especially for bodily injury, but it also influences the loss of properties. Figure 5.13 shows that the medium line (around 1 ) is above and below the confidence intervals. It shows even though all data have been brought to present worth, time still has great effects so the present worth does not cover the time effects. So the final model for claim sizes has multiplication factor $C=0.5,8$ postal categories and only $d_{1}$ included in the model.

Like for the model for claim frequency, spatial trend in the claim sizes will be examined by analyzing the results from the gamma model graphically, see Figure 5.14. This figure shows that the residence of policyholders has a small effect on the total claim sizes. The total claim sizes are between 80000 and 90000 . This corresponds to the result in Table 5.8 which shows the spatial factor has almost no effect. But like before the postal category matrix, $\eta$ has small effect. More accurate pictures will not be shown for this model since Figure 5.14 shows results accurate enough.

Figure 5.13: The temporal factor $d_{1}$ as a function of time. This figure shows the exponential value of the factor, i.e. $\exp \left(d_{1}\right)$.

Figure 5.14: Expected total claim size for all postal codes with $95 \%$ posterior interval.
The postal codes are on the $x$-axis and the claim size are on the $y$-axis.

### 5.4. Expected compensation

Expected compensation cost, introduced in Chapter 4, is based on the combination of results from the Poisson and the gamma models. The expected compensation is the amount the insurance company has to pay per policy year for each postal code in the country.

Like Figure 5.15 shows, the expected compensation is in context with claim fre-

Figure 5.15: Expected compensation cost for all postal codes along with 95\% posterior interval.
quency and claim sizes. The total compensation cost depends on residence of policyholder. The highest value is in the capital area and gets lower when you get to the countryside. Figures E.11-E. 20 in Appendix E show more accurate results. Figure E. 11 and E. 12 show the expected cost is around 6000, but in Figure E. 13 it starts to get lower and in Figure E. 15 the expected cost is stable around 4000. It stays stable except in few cases where the cost raises a bit in postal codes belonging to the postal category Large urban regions and becomes closer to 6000 . As mentioned in Section 5.2 there are a few postal codes that have large posterior interval. Those postal codes usually have small amount of claims, but during some years the number of claims rises (but still amount of policyholders similar) and is higher compared to other years and nearby postal codes.

## 6. Discussion

The aim of this study is to find the expected compensation cost the insurance company needs to pay because of property loss due to car accidents. The information given are based on postal codes and the expected compensation cost is estimated for each postal code in the country. The main goal is to evaluate if the residence of policyholders influence the result, by using a regional factor. Also it was examined whether a temporal factor would improve the model. To improve the regional factor, postal codes were grouped into eight categories depending on type and results examined for each category. In this thesis two kind of neighbor structures are used in the proposed models, one for time and other for postal codes.

Today the insurance company divides the postal codes in the country into a few risk zones. The insurance premium depends, among other factors, on these zones. The matrix describing the neighbor structure is such that it is easy to change if needed. The same holds true for the postal category matrix. The postal category matrix allows both changes on the number of categories and changes of postal codes within each category. Therefore it is easy for the insurance company to change the zones and postal codes within each zone if needed.

The expected compensation cost is based on models for the expected claim frequency and expected total claim size. Results from these two models are combined to get the expected compensation cost. The results from the research can be summarized as follows

- Claim frequency
- Dependence between claim frequency and the residence of policyholders.
- Highest number at the capital area and lowest in the country side.
- Includes both a temporal factor and a regional factor where the regional factor has a great influence but the temporal factor has a small influence.
- In accordance to DIC comparison the temporal factor is included in case of years with high claim frequency. It does not make the model less qualified.
- Claim size
- Claim size depends only on postal category but not on individual postal codes.
- Claim size is similar for the postal categories.
- Includes a temporal factor.
- In accordance to DIC comparison the spatial factor (after taking postal categories into account) has little influence and was removed from the model. The temporal factor has great influence despite all data have been brought to present worth.
- Expected compensation
- In context with the results of claim frequency and claim size.
- Highest cost in the capital area, lower in the countryside.

Results from the eight postal categories are in context with the results from the models. The expected compensation cost is highest for category 1 which are postal codes in Reykjavík. The cost is a bit lower for category 2 and 3 or Reykjavík urban regions and large urban regions. It gets lower and in small urban regions and rural areas the expected compensation is about $50 \%$ lower than in Reykjavík. What makes interest is that the expected compensation cost is a bit higher in rural areas than rural near highway but that is mainly due to higher claim size. For the expected compensation cost the average lower bound multiplication factor is 0.6341 and the average upper bound multiplication factor is 1.5083 which gives an idea about the precision of the expected compensation cost.

According to these results there is a spatial trend in the expected compensation cost so it can be justified to price car insurances according to the residence of the policyholder. The results of this study show the zone separation like the insurance company is using today is not out-of-date but the postal codes can be rearranged in the zones according to the results.

## 7. Future studies

When working on this thesis, ideas on future projects came up. The main ideas are:

- Further development of the postal categories based on results for each postal code.
- Use a Poisson model without overdispersion.
- Use zero-inflated Poisson model.
- Investigate overdispersed Poisson model where $\exp \left(\varepsilon_{i t}\right)$ follows a gamma distribution.
- For more accurate data it would be interesting to analyze data on individual basis and take into account variables such as
- Type of car
- Gender of policyholder
- Age of policyholder
- Age of car
- Accident history of policyholder
to name a few.
- Analysis data for risk categories with few policyholders.

## A.2. Regional neighborhood structure

The matrix for regional neighborhood is $N \times N$ matrix, where N is the total number of postal codes. Because of its size only a matrix which shows the neighbors to each postal code will be expressed to describe the neighbors. Instead of 0 and 1 that connects neighbors, the actual postal codes are shown, see Table A.2. Nonetheless the original regional neighborhood matrix is similar to the temporal neighborhood matrix in Table A.1.
Table A.2: Regional neighbors.

## B. Calculations for $\sigma_{i t}^{2}$

Approximation for $\sigma_{i t}^{2}$

$$
N_{i t} \sim \operatorname{Poisson}\left(e_{i t} \cdot \mathrm{r}\right),
$$

where r is the average frequency per policy year, $r=\exp \left(C_{1}\right)$ and $C_{1}=\log (\theta)$.

$$
\hat{r}=\frac{\sum_{i} \sum_{t} N_{i t}}{\sum_{i} \sum_{t} e_{i t}}
$$

where $\hat{C}_{1}=\log (\hat{r})$ and $\hat{C}_{2}=\exp \left(-\hat{C}_{1}\right)$.

$$
\mu=X^{T} \beta+a_{1}+a_{2}+\log e_{i t}
$$

$X^{T} \beta \simeq C_{1}, a_{1} \simeq 0$ and $a_{2} \simeq 0$, which gives

$$
\begin{gathered}
\exp (\mu) \simeq e_{i t} \exp \left(C_{1}\right) \\
\exp (\mu) \exp \left(2 \sigma_{i t}^{2}\right)-\exp (\mu) \exp \left(\sigma_{i t}^{2}\right)+\exp \left(\sigma_{i t}^{2} / 2\right)=(1+\delta) \\
\left.\exp \left(2 \sigma_{i t}^{2}\right)-\exp \left(\sigma_{i t}^{2}\right)+\exp \left(\sigma_{i t}^{2} / 2-\mu\right)=(1+\delta) \exp \right)(\mu) \\
\exp \left(2 \sigma_{i t}^{2}\right)-\exp \left(\sigma_{i t}^{2}\right)=\left(1+\delta-\exp \left(\sigma_{i t}^{2} / 2\right)\right) \exp (-\mu)
\end{gathered}
$$

or

$$
\exp \left(2 \sigma_{i t}^{2}\right)-\exp \left(\sigma_{i t}^{2}\right) \simeq \exp (-\mu)=\frac{1}{e_{i t}} \exp \left(-C_{1}\right)
$$

which gives the second order equation

$$
\exp \left(2 \sigma_{i t}^{2}\right)-\exp \left(\sigma_{i t}^{2}\right)-\frac{C_{2}}{e_{i t}}=0
$$

Then

$$
\exp \left(\sigma_{i t}^{2}\right)=\frac{1+\sqrt{1+4 C_{2} / e_{i t}}}{2}
$$

and

$$
\sigma_{i t}^{2}=\log \left(\frac{1}{2}+\frac{1}{2} \sqrt{1+4 C_{2} / e_{i t}}\right)=\log \left(\frac{1}{2}+\frac{1}{2} \sqrt{1+4 /\left(r+e_{i t}\right)}\right)
$$

## C. Conditional distributions

Conditional distributions for parameters in model for claim frequency:

$$
\begin{aligned}
& \theta_{i t}^{*}, \mathrm{i}=\mathrm{i}, \ldots, \mathrm{~J} \text { and } \mathrm{t}=1, \ldots, \mathrm{~T} \\
& \qquad p\left(\theta_{i t}^{*} \mid r e s t\right) \\
& \propto p\left(N_{i t} \mid \theta_{i t}^{*}\right) \times p\left(\theta_{i t}^{*} \mid a_{1}, a_{2}, \beta, \sigma_{\varepsilon, i t}^{2}\right) \\
& \\
& \propto \operatorname{Poisson}\left[N_{i t} \mid e_{i t} \exp \left(\theta_{i t}^{*}\right)\right] \times \mathrm{N}\left(\theta_{i t}^{*} \mid \mu_{i t}, \sigma_{\varepsilon, i t}^{2}\right) \\
& \\
& \propto e_{i t}^{N_{i t}} \exp \left(N_{i t} \theta_{i t}^{*}\right) \exp \left[-e_{i t} \exp \left(\theta_{i t}^{*}\right)\right] \exp \left[-\frac{1}{2 \sigma_{\varepsilon, i t}^{2}}\left(\theta_{i t}^{*}-\mu_{i t}\right)^{2}\right]
\end{aligned}
$$

where

$$
\mu_{i t}=x_{i}^{T} \beta+Z_{1} a_{1}+Z_{2} a_{2}
$$

so
and the proposal variance is

$$
\operatorname{Var}\left(\theta_{i t}^{*}\right)_{p r o p} \propto \frac{1}{N_{i t}+1 / \sigma_{\varepsilon, i t}^{2}}
$$

Conditional distribution of $\beta$

$$
\begin{aligned}
p(\beta \mid \mathrm{rest}) \propto & p\left(\theta^{*} \mid a_{1}, a_{2}, \beta, \Sigma_{\varepsilon}\right) \times p(\beta) \\
\propto & \mathrm{N}\left(\theta^{*} \mid \gamma, \Sigma_{\varepsilon} I\right) \times \mathrm{N}\left(\beta \mid \mu_{\beta}, \sigma_{\beta}^{2} I\right) \\
& \propto \exp \left[-\frac{1}{2}\left(\theta^{*}-\gamma\right)^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-\gamma\right)\right] \exp \left[-\frac{1}{2 \sigma_{\beta}^{2}}\left(\beta-\mu_{\beta}\right)^{2}\right] \\
\log p(\beta \mid \text { rest })= & C_{0}-\frac{1}{2}\left[\beta^{T} X^{T} \Sigma_{\varepsilon}^{-1} X \beta-2 \beta^{T} X^{T}\left(\theta^{*}-Z_{1} a_{1}-Z_{2} a_{2}\right)\right]-\frac{1}{2}\left(\beta-\mu_{\beta}\right)^{T} \Sigma_{\beta}^{-1}\left(\beta-\mu_{\beta}\right)
\end{aligned}
$$

where

$$
\gamma=X \beta+Z_{1} a_{1}+Z_{2} a_{2}
$$

since

$$
p(\beta \mid \text { rest })=N\left(\beta \mid \mu_{\beta}, \sigma_{\beta}\right)
$$

the covariance matrix is

$$
\Sigma_{\beta}=\left(X^{T} \Sigma_{\varepsilon}^{-1} X+\sigma_{\beta}^{2} I\right)^{-1}
$$

and the mean is

$$
\mu_{\beta}=\Sigma_{\beta}\left(X^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-Z 1 a 1-Z 2 a 2\right)+\sigma_{\beta}^{-2} \mu_{\beta}\right)
$$

The conditional distribution of $a_{1}$

$$
\begin{aligned}
p\left(a_{1} \mid \text { rest }\right) \propto & p\left(\theta^{*} \mid a_{1}, a_{2}, \beta, \Sigma_{\varepsilon}\right) \times p\left(a_{1} \mid \phi_{1}, \tau_{1}^{2}\right) \\
\propto & \mathrm{N}\left(\theta^{*} \mid \gamma, \Sigma_{\varepsilon} I\right) \times \mathrm{N}\left(a_{1} \mid \overline{0}, \tau_{1}^{2}\left(I-\phi_{1} C_{1}\right)^{-1} M_{1}\right) \\
\propto & \exp \left[-\frac{1}{2}\left(\theta^{*}-\gamma\right)^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-\gamma\right)\right] \\
& \times \exp \left[-\frac{1}{2 \tau_{1}^{2}} a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}\right] \\
\log p\left(a_{1} \mid \text { rest }\right)= & C_{0}-\frac{1}{2}\left[a_{1}^{T} Z_{1}^{T} \Sigma_{\varepsilon}^{-1} Z_{1} a_{1}-2 a_{1}^{T} Z_{1}^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-X \beta-Z_{2} a_{2}\right)\right] \\
& -\frac{1}{2 \tau_{1}} a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}
\end{aligned}
$$

where

$$
\gamma=X \beta+Z_{1} a_{1}+Z_{2} a_{2}
$$

And since

$$
p\left(a_{1} \mid \text { rest }\right)=N\left(a_{1} \mid \mu_{a 1}, \Sigma_{a 1}\right)
$$

the covariance matrix is

$$
\Sigma_{a 1}=\left[Z_{1}^{T} \Sigma_{\varepsilon}^{-1} Z_{1}+\tau_{1}^{2}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right)\right]^{-1}
$$

and the mean is

$$
\mu_{a 1}=\Sigma_{a 1} Z_{1}^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-X \beta-Z_{2} a_{2}\right) .
$$

Then $a_{1}$ is adjusted so that $\Sigma_{j} a_{1, j}=0$ and $Q^{-1}=\Sigma_{a 1}$ so

$$
a_{1}^{*}=a_{1}-Q^{-1} A^{T}\left(A Q^{-1} A^{T}\right)^{-1}\left(A a_{1}-0\right),
$$

where $A$ is a vector of ones.

And similar, the conditional distribution of $a_{2}$ is

$$
\begin{aligned}
p\left(a_{2} \mid \text { rest }\right) \propto & p\left(\theta^{*} \mid a_{1}, a_{2}, \beta, \Sigma_{\varepsilon}\right) \times p\left(a_{2} \mid \phi_{2}, \tau_{2}^{2}\right) \\
\propto & \mathrm{N}\left(\theta^{*} \mid \gamma, \Sigma_{\varepsilon} I\right) \times \mathrm{N}\left(a_{2} \mid \overline{0}, \tau_{2}^{2}\left(I-\phi_{2} C_{2}\right)^{-1} M_{2}\right) \\
\propto & \exp \left[-\frac{1}{2}\left(\theta^{*}-\gamma\right)^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-\gamma\right)\right] \\
& \times \exp \left[-\frac{1}{2 \tau_{2}^{2}} a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}\right] \\
\log p\left(a_{2} \mid \text { rest }\right)= & C_{0}-\frac{1}{2}\left[a_{2}^{T} Z_{2}^{T} \Sigma_{\varepsilon}^{-1} Z_{2} a_{2}-2 a_{2}^{T} Z_{2}^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-X \beta-Z_{1} a_{1}\right)\right] \\
& -\frac{1}{2 \tau_{1}} a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}
\end{aligned}
$$

where

$$
\gamma=X \beta+Z_{1} a_{1}+Z_{2} a_{2}
$$

And since

$$
p\left(a_{2} \mid \text { rest }\right)=N\left(a_{2} \mid \mu_{a 2}, \Sigma_{a 2}\right)
$$

the covariance matrix is

$$
\Sigma_{a 2}=\left[Z_{2}^{T} \Sigma_{\varepsilon}^{-1} Z_{2}+\tau_{2}^{2}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right)\right]^{-1}
$$

and the mean is

$$
\mu_{a 2}=\Sigma_{a 2} Z_{2}^{T} \Sigma_{\varepsilon}^{-1}\left(\theta^{*}-X \beta-Z_{1} a_{1}\right)
$$

Then $a_{2}$ is adjusted so that $\Sigma_{j} a_{2, j}=0$ and $Q^{-1}=\Sigma_{a 2}$ so

$$
a_{2}^{*}=a_{2}-Q^{-1} A^{T}\left(A Q^{-1} A^{T}\right)^{-1}\left(A a_{2}-0\right),
$$

where A is a vector of ones.
The conditional distribution of $\tau_{1}^{2}$ :

$$
\begin{aligned}
p\left(\tau_{1}^{2} \mid \text { rest }\right) & \propto p\left(a_{1} \mid \phi_{1}, \tau_{1}^{2}\right) \times p\left(\tau_{1}^{2}\right) \\
& \propto \mathrm{N}\left[a_{1} \mid \overline{0}, \tau_{1}^{2}\left(I-\phi_{1} C_{1}\right)^{-1} M_{1}\right] \times \operatorname{Inv}-\chi^{2}\left(\nu_{\tau 1}, s_{\tau 1}^{2}\right) \\
& \propto\left(\tau_{1}^{2}\right)^{-n_{1} / 2} \exp \left[-\frac{1}{2 \tau_{1}^{1}} a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}\right]\left(\tau_{1}^{2}\right)^{-\left(\nu_{\tau 1} / 2+1\right)} \exp \left(-\frac{\nu_{\tau 1} s_{\tau 1}^{2}}{2 \tau_{1}^{2}}\right) \\
& \propto\left(\tau_{1}^{2}\right)^{-\left[\left(n_{1}+\nu_{\tau 1}\right) / 2+1\right]} \exp \left\{-\frac{1}{2 \tau_{1}^{2}}\left[\nu_{\tau 1} s_{\tau 1}^{2}+a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}\right]\right\} \\
& \propto \operatorname{Inv}-\chi^{2}\left\{n_{1}+\nu_{\tau 1},\left(n_{1}+\nu_{\tau 1}\right)^{-1}\left[\nu_{\tau 1} s_{\tau 1}^{2}+a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}\right]\right\}
\end{aligned}
$$

The conditional distribution of $\phi_{1}$ :

$$
\begin{aligned}
p\left(\phi_{1} \mid \text { rest }\right) & \propto p\left(a_{1} \mid \phi_{1}, \tau_{1}^{2}\right) \times p\left(\phi_{1}\right) \\
& \propto \mathrm{N}\left[a_{1} \mid \overline{0}, \tau_{1}^{2}\left(I-\phi_{1} C_{1}\right)^{-1} M_{1}\right] \times \operatorname{beta}\left(\phi_{1} \mid \alpha_{\phi 1}, \beta_{\phi 1}\right) \\
& \propto\left|I-\phi_{1} C_{1}\right|^{1 / 2} \exp \left[-\frac{1}{2 \tau_{1}^{2}} a_{1}^{T}\left(M_{1}^{-1}-\phi_{1} M_{1}^{-1} C_{1}\right) a_{1}\right] \times \phi_{1}^{\alpha_{\phi 1}-1}\left(1-\phi_{1}\right)^{\beta_{\phi 1}-1}
\end{aligned}
$$

Let $\lambda_{1(j)}$ be the ordered eigenvalue of $C_{1}$, then

$$
\begin{gathered}
\left|I-\phi_{1} C_{1}\right|=\prod_{j=1}^{n_{1}}\left(1-\phi_{1} \lambda_{1(j)}\right) \\
\log p\left(\phi_{1} \mid r e s t\right)=C_{0}+0.5 \sum_{j=1}^{n_{1}} \log \left(1-\phi_{1} \lambda_{1(j)}\right)+0.5 \phi_{1} \tau_{1}^{-2} a_{1}^{T}\left(M_{1}^{-1} C_{1}\right) a_{1} \\
+\left(\alpha_{\phi 1}-1\right) \log \left(\phi_{1}\right)+\left(\beta_{\phi 1}-1\right) \log \left(1-\phi_{1}\right)
\end{gathered}
$$

The conditional distribution of $\tau_{2}^{2}$ :

$$
\begin{aligned}
p\left(\tau_{2}^{2} \mid \text { rest }\right) & \propto p\left(a_{2} \mid \phi_{2}, \tau_{2}^{2}\right) \times p\left(\tau_{2}^{2}\right) \\
& \propto \mathrm{N}\left(a_{2} \mid \overline{0}, \tau_{2}^{2}\left(I-\phi_{2} C_{2}\right)^{-1} M_{2}\right) \times \operatorname{Inv}-\chi^{2}\left(\nu_{\tau 2}, s_{\tau 2}^{2}\right) \\
& \propto\left(\tau_{2}^{2}\right)^{-n_{2} / 2} \exp \left[-\frac{1}{2 \tau_{2}^{2}} a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}\right] \times\left(\tau_{2}^{2}\right)^{-\left(\nu_{\tau 2} / 2+1\right)} \exp \left(-\frac{\nu_{\tau 2} s_{\tau 2}^{2}}{2 \tau_{2}^{2}}\right) \\
& \propto\left(\tau_{2}^{2}\right)^{-\left[\left(n_{2}+\nu_{\tau 2}\right) / 2+1\right]} \exp \left\{-\frac{1}{2 \tau_{2}^{2}}\left[\nu_{\tau 2} s_{v}^{2}+a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}\right]\right\} \\
& \propto \operatorname{Inv}-\chi^{2}\left\{n_{2}+\nu_{\tau 2},\left(n_{2}+\nu_{\tau 2}\right)^{-1}\left[\nu_{\tau 2} s_{\tau 2}^{2}+a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}\right]\right\}
\end{aligned}
$$

The conditional distribution of $\phi_{2}$ :

$$
\begin{aligned}
p\left(\phi_{2} \mid \text { rest }\right) & \propto p\left(a_{2} \mid \phi_{2}, \tau_{2}^{2}\right) \times p\left(\phi_{2}\right) \\
& \propto \mathrm{N}\left(a_{2} \mid \overline{0}, \tau_{2}^{2}\left(I-\phi_{2} C_{2}\right)^{-1} M_{2}\right) \times \operatorname{beta}\left(\phi_{2} \mid \alpha_{\phi 2}, \beta_{\phi 2}\right) \\
& \propto\left|I-\phi_{2} C_{2}\right|^{1 / 2} \exp \left[-\frac{1}{2 \tau_{2}^{2}} a_{2}^{T}\left(M_{2}^{-1}-\phi_{2} M_{2}^{-1} C_{2}\right) a_{2}\right] \times \phi_{2}^{\alpha_{\phi 2}-1}\left(1-\phi_{2}\right)^{\beta_{\phi 2}-1}
\end{aligned}
$$

Let $\lambda_{2(j)}$ be the ordered eigenvalue of $C_{2}$, then

$$
\left|I-\phi_{2} C_{2}\right|=\prod_{j=1}^{n_{2}}\left(1-\phi_{2} \lambda_{2(j)}\right)
$$

$$
\begin{aligned}
\log p\left(\phi_{2} \mid \text { rest }\right) & =C_{0}+0.5 \sum_{j=1}^{n_{2}} \log \left(1-\phi_{2} \lambda_{2(j)}\right)+0.5 \phi_{2} \tau_{2}^{-2} a_{2}^{T}\left(M_{2}^{-1} C_{2}\right) a_{2} \\
& +\left(\alpha_{\phi 2}-1\right) \log \left(\phi_{2}\right)+\left(\beta_{\phi 2}-1\right) \log \left(1-\phi_{2}\right)
\end{aligned}
$$

Following, conditional distributions for all parameters in the claim size model:
The conditional distribution of $\eta$

$$
\begin{aligned}
P(\eta \mid \text { rest }) & \propto p\left(S \mid d_{1}, d_{2}, \eta, \alpha, N\right) \times p(\eta) \\
& \propto \prod_{i=1}^{J} \prod_{t=1}^{T} \operatorname{gamma}\left[S_{i t} \mid N_{i t} \exp \left(\lambda_{i t}\right), \frac{N_{i t}}{\alpha} \exp \left(2 \lambda_{i t}\right)\right] \times \mathrm{N}\left(\eta \mid \mu_{\eta}, \Sigma_{\eta} I\right) \\
& \propto \prod_{i=1}^{J} \prod_{t=1}^{T}\left[\alpha \exp \left(-\lambda_{i t}\right)\right]^{\alpha N_{i t}} \exp \left[-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right] \times \exp \left[\frac{-1}{2}\left(\eta-\mu_{\eta}\right)^{T} \Sigma_{\eta}^{-1}\left(\eta-\mu_{\eta}\right)\right] \\
\log (\eta \mid \text { rest }) & =\sum_{i=1}^{J} \sum_{t=1}^{T}\left\{\left(\alpha N_{i t}\right) \log \left[\alpha \exp \left(-\lambda_{i t}\right)\right]-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right\}-\frac{1}{2}\left(\eta-\mu_{\eta}\right)^{T} \Sigma_{\eta}^{-1}\left(\eta-\mu_{\eta}\right)
\end{aligned}
$$

where

$$
\lambda_{i t}=x_{i}^{T} \eta+d_{1, t}+d_{2, i}
$$

And the proposal variance is

$$
\operatorname{Var}(\eta)_{\text {prop }} \propto \frac{1}{\alpha \sum_{i=1}^{J} \sum_{t=1}^{T} N_{i t} x_{i}}+\frac{1}{\sigma_{\eta}^{2}}
$$

Conditional distribution of $d_{1, t}, t=1, \ldots, T$

$$
\begin{aligned}
P\left(d_{1, t} \mid \text { rest }\right) \propto & p\left(S \mid d_{1}, d_{2}, \eta, \alpha, N\right) \times p\left(d_{1} \mid \kappa_{1}^{2}, \zeta_{1}\right) \\
\propto & \prod i=1 J \operatorname{gamma}\left[S_{i t} \mid N_{i t} \exp \left(\lambda_{i t}\right), \frac{N_{i t}}{\alpha} \exp \left(2 \lambda_{i t}\right)\right] \\
& \times \mathrm{N}\left(d_{1, t} \mid \sum_{k=1, k \neq t}^{T} C_{1, t k} d_{1, k}, M_{1, t t} \kappa_{1}^{2}\right) \\
\propto & \prod i=1 J \alpha \exp \left(-\lambda_{i t}\right)^{\alpha N_{i t}} \exp \left[-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right] \\
& \times \exp \left[\frac{-1}{2 M_{1, t t \kappa_{1}^{2}}}\left(d_{1, t}-\sum_{k=1, k \neq t}^{T} C_{1, t k} d_{1, k}\right)^{2}\right] \\
\propto & \prod i=1 J \exp \left(-\alpha N_{i t} \lambda_{i t}\right) \exp \left[-\alpha S_{i t} \exp \left(-\lambda_{i t}\right)\right] \\
& \times \exp \left[\frac{-1}{2 M_{1, t t \kappa_{1}^{2}}}\left(d_{1, t}-\sum_{k=1, k \neq t}^{T} C_{1, t k} d_{1, k}\right)^{2}\right] \\
\log p\left(d_{1, t} \mid \text { rest }\right)= & \sum_{i=1}^{J}\left[-\alpha N_{i t} \exp \left(\lambda_{i t}\right)-\alpha S_{i t} \exp \left(-\lambda_{i t}\right)\right]-\frac{-1}{2 M_{1, t t \kappa_{1}^{2}}}\left(d_{1, t}-\sum_{k=1, k \neq t}^{T} C_{1, t k} d_{1, k}\right)^{2}
\end{aligned}
$$

where

$$
\lambda_{i t}=x_{i}^{T} \eta+d_{1, t}+d_{2, i}
$$

And the proposal variance is

$$
\operatorname{Var}\left(d_{1, t}\right)_{\text {prop }} \propto \frac{1}{\alpha \sum_{i=1}^{J} N_{i t}+\frac{1}{M_{1, t t} \kappa_{1}^{2}}}
$$

Conditional distribution of $d_{2, i}, i=1, \ldots, J$

$$
\begin{aligned}
P\left(d_{2, i} \mid \text { rest }\right) \propto & p\left(S \mid d_{1}, d_{2}, \eta, \alpha, N\right) \times p\left(d_{2} \mid \kappa_{2}^{2}, \zeta_{2}\right) \\
\propto & \prod t=1 T \operatorname{gamma}\left[S_{i t} \mid N_{i t} \exp \left(\lambda_{i t}\right), \frac{N_{i t}}{\alpha} \exp \left(2 \lambda_{i t}\right)\right] \\
& \times \mathrm{N}\left(d_{2, i} \mid \sum_{k=1, k \neq i}^{T} C_{2, i k} d_{2, k}, M_{2, i i} \kappa_{2}^{2}\right) \\
\propto & \prod t=1 T \alpha \exp \left(-\lambda_{i t}\right)^{\alpha N_{i t}} \exp \left[-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right] \\
& \times \exp \left[\frac{-1}{2 M_{2, i i} \kappa_{2}^{2}}\left(d_{2, i}-\sum_{k=1, k \neq i}^{T} C_{2, i k} d_{2, k}\right)^{2}\right] \\
\propto & \prod t=1 T \exp \left(-\alpha N_{i t} \lambda_{i t}\right) \exp \left[-\alpha S_{i t} \exp \left(-\lambda_{i t}\right)\right] \\
& \times \exp \left[\frac{-1}{2 M_{2, i i} \kappa_{2}^{2}}\left(d_{2, i}-\sum_{k=1, k \neq i}^{T} C_{2, i k} d_{2, i}\right)^{2}\right]
\end{aligned}
$$

$\log P\left(d_{2, i} \mid\right.$ rest $)=\sum_{t=1}^{T}\left[-\alpha N_{i t} \exp \left(\lambda_{i t}\right)-\alpha S_{i t} \exp \left(-\lambda_{i t}\right)\right]-\frac{-1}{2 M_{2, i i} \kappa_{2}^{2}}\left(d_{2, i}-\sum_{k=1, k \neq i}^{T} C_{2, i k} d_{2, k}\right)^{2}$
where

$$
\lambda_{i t}=x_{i}^{T} \eta+d_{1, t}+d_{2, i}
$$

And the proposal variance is

$$
\operatorname{Var}\left(d_{2, i}\right)_{\text {prop }} \propto \frac{1}{\alpha \sum_{t=1}^{T} N_{i t}+\frac{1}{M_{2, i i} \kappa_{1}^{2}}}
$$

Conditional distribution of $\kappa_{1}^{2}$

$$
\begin{aligned}
P\left(\kappa_{1}^{2} \mid \text { rest }\right) & \propto p\left(d_{1} \mid \zeta_{1}, \kappa_{1}^{2}\right) \times p\left(\kappa_{1}^{2}\right) \\
& \propto \mathrm{N}\left[d_{1} \mid \overline{0}, \kappa_{1}^{2}\left(I-\zeta_{1} C_{1}\right)^{-1} M_{1}\right] \times \operatorname{Inv}-\chi^{2}\left(\nu_{\kappa 1}, S_{\kappa 1}^{2}\right) \\
& \propto\left(\kappa_{1}^{2}\right)^{-n_{1} / 2} \exp \left[\frac{-1}{2 \kappa_{1}^{2}} d_{1}^{T}\left(M_{1}^{-1}-\zeta_{1} M_{1}^{-1} C_{1}\right) d_{1}\right] \times\left(\kappa_{1}^{2}\right)^{-\left(\nu_{\kappa_{1}} / 2+1\right)} \exp \left(-\frac{\nu_{\kappa 1} S_{\kappa 1}^{2}}{2 \kappa_{1}^{1}}\right) \\
& \propto\left(\kappa_{1}^{2}\right)^{-\left(\frac{n_{1} \nu_{\kappa 1}}{2}+1\right)} \exp \left\{\frac{-1}{2 \kappa_{1}^{2}}\left[\nu_{\kappa 1} S_{\kappa 1}^{2}+d_{1}^{T}\left(M_{1}^{-1}-\zeta_{1} M_{1}^{-1} C_{1}\right) d_{1}\right]\right\} \\
& \propto \operatorname{Inv}-\chi^{2}\left\{n_{1}+\nu_{\kappa 1},\left(n_{1}+\nu_{\kappa 1}\right)^{-1}\left[\nu_{\kappa 1} S_{\kappa 1}^{2}+d_{1}^{T}\left(M_{1}^{-1}-\zeta_{1} M_{1}^{-1} C_{1}\right) d_{1}\right]\right\}
\end{aligned}
$$

Conditional distribution of $\zeta_{1}$

$$
\begin{aligned}
P\left(\zeta_{1} \mid \text { rest }\right) & \propto p\left(d_{1} \mid \zeta_{1}, \kappa_{1}^{2}\right) \times p\left(\zeta_{1}\right) \\
& \propto \mathrm{N}\left[d_{1} \mid \overline{0}, \kappa_{1}^{2}\left(I-\zeta_{1} C_{1}\right)^{-1} M_{1}\right] \times \operatorname{beta}\left(\zeta_{1} \mid \alpha_{\zeta 1}, \beta_{\zeta 1}\right) \\
& \propto\left|I-\zeta_{1} C_{1}\right|^{1 / 2} \exp \left[\frac{-1}{2 \kappa_{1}^{2}} d_{1}^{T}\left(M_{1}^{-1}-\zeta_{1} M_{1}^{-1} C_{1}\right) d_{1}\right] \times \zeta_{1}^{\alpha_{\zeta 1}-1}\left(1-\zeta_{1}\right)^{\beta_{\zeta 1}-1}
\end{aligned}
$$

Let $\lambda_{1(j)}$ be the ordered eigenvalue of $C_{1}$, then

$$
\left|I-\zeta_{1} C_{1}\right|=\prod_{j=1}^{n_{1}}\left(1-\zeta_{1} \lambda_{1(j)}\right)
$$

and
$\log P\left(\zeta_{1} \mid\right.$ rest $)=C_{0}+\frac{1}{2} \sum_{j=1}^{n_{1}} \log \left(1-\zeta_{1} \lambda_{1(j)}\right)+\frac{\zeta_{1}}{2 \kappa_{1}^{2}} d_{1}^{T}\left(M_{1}^{-1} C_{1}\right) d_{1}+\left(\alpha_{\zeta 1}-1\right) \log \zeta_{1}+\left(\beta_{\zeta 1}-1\right) \log \left(1-\zeta_{1}\right)$

Conditional distribution of $\kappa_{2}^{2}$

$$
\begin{aligned}
P\left(\kappa_{2}^{2} \mid \text { rest }\right) & \propto p\left(d_{2} \mid \zeta_{2}, \kappa_{2}^{2}\right) \times p\left(\kappa_{2}^{2}\right) \\
& \propto \mathrm{N}\left[d_{2} \mid \overline{0}, \kappa_{2}^{2}\left(I-\zeta_{2} C_{2}\right)^{-1} M_{2}\right] \times \operatorname{Inv}-\chi^{2}\left(\nu_{\kappa 2}, S_{\kappa 2}^{2}\right) \\
& \propto\left(\kappa_{2}^{2}\right)^{-n_{2} / 2} \exp \left[\frac{-1}{2 \kappa_{2}^{2}} d_{2}^{T}\left(M_{2}^{-1}-\zeta_{2} M_{2}^{-1} C_{2}\right) d_{2}\right]\left(\kappa_{2}^{2}\right)^{-\left(\nu_{\kappa 2} / 2+1\right)} \exp \left(-\frac{\nu_{\kappa 2} S_{\kappa 2}^{2}}{2 \kappa_{2}^{2}}\right) \\
& \propto\left(\kappa_{2}^{2}\right)^{-\left(\frac{n_{2} \nu_{\kappa 2}}{2}+1\right)} \exp \left\{\frac{-1}{2 \kappa_{2}^{2}}\left[\nu_{\kappa 2} S_{\kappa 2}^{2}+d_{2}^{T}\left(M_{2}^{-1}-\zeta_{2} M_{2}^{-1} C_{2}\right) d_{2}\right]\right\} \\
& \propto \operatorname{Inv}-\chi^{2}\left\{n_{2}+\nu_{\kappa 2},\left(n_{2}+\nu_{\kappa 2}\right)^{-1}\left[\nu_{\kappa 2} S_{\kappa 2}^{2}+d_{2}^{T}\left(M_{2}^{-1}-\zeta_{2} M_{2}^{-1} C_{2}\right) d_{2}\right]\right\}
\end{aligned}
$$

Conditional distribution of $\zeta_{2}$

$$
\begin{aligned}
P\left(\zeta_{2} \mid \text { rest }\right) & \propto p\left(d_{2} \mid \zeta_{2}, \kappa_{2}^{2}\right) \times p\left(\zeta_{2}\right) \\
& \propto \mathrm{N}\left[d_{2} \mid \overline{0}, \kappa_{2}^{2}\left(I-\zeta_{2} C_{2}\right)^{-1} M_{2}\right] \times \operatorname{beta}\left(\zeta_{2} \mid \alpha_{\zeta 2}, \beta_{\zeta 2}\right) \\
& \propto\left|I-\zeta_{2} C_{2}\right|^{1 / 2} \exp \left[\frac{-1}{2 \kappa_{2}^{2}} d_{2}^{T}\left(M_{2}^{-1}-\zeta_{2} M_{2}^{-1} C_{2}\right) d_{2}\right] \times \zeta_{2}^{\alpha_{\zeta 2}-1}\left(1-\zeta_{2}\right)^{\beta_{\zeta 2}-1}
\end{aligned}
$$

Let $\lambda_{2(j)}$ be the ordered eigenvalue of $C_{2}$, then

$$
\left|I-\zeta_{2} C_{2}\right|=\prod_{j=1}^{n_{2}}\left(1-\zeta_{2} \lambda_{2(j)}\right)
$$

and
$\log p\left(\zeta_{2} \mid\right.$ rest $)=C_{0}+\frac{1}{2} \sum_{j=1}^{n_{2}} \log \left(1-\zeta_{2} \lambda_{2(j)}\right)+\frac{\zeta_{2}}{2 \kappa_{2}^{2}} d_{2}^{T}\left(M_{2}^{-1} C_{2}\right) d_{2}+\left(\alpha_{\zeta 2}-1\right) \log \zeta_{2}+\left(\beta_{\zeta 2}-1\right) \log \left(1-\zeta_{2}\right)$

And finally, the conditional distribution of $\alpha$

$$
\begin{aligned}
P(\alpha \mid \text { rest }) \propto & p\left(S \mid d_{1}, d_{2}, \eta, \alpha, N\right) \times p\left(\alpha \mid \alpha_{0}, \beta_{0}\right) \\
\propto & \prod_{i=1}^{J} \prod_{t=1}^{T} \operatorname{gamma}\left[S_{i t} \mid N_{i t} \exp \left(\lambda_{i t}\right), \frac{N_{i t}}{\alpha} \exp \left(2 \lambda_{i t}\right)\right] \times \operatorname{gamma}\left(\alpha_{0}, \beta_{0}\right) \\
\propto & \prod_{i=1}^{J} \prod_{t=1}^{T} \frac{1}{\gamma\left(\alpha N_{i t}\right)}\left[\alpha \exp \left(-\lambda_{i t}\right)\right]^{\alpha N_{i t}} S_{i t}^{\left(\alpha N_{i t}\right)-1} \exp \left[-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right] \\
& \times \frac{\beta_{0}^{\alpha_{0}} \alpha_{0}}{\alpha_{0}-1} \exp \left(-\beta_{0} \alpha\right) \\
\log (\alpha \mid \text { rest })= & \sum_{i=1}^{J} \sum_{t=1}^{T}\left\{-\log \operatorname{gamma}\left(\alpha N_{i t}\right)+\left(\alpha N_{i t}\right) \log \left[\alpha \exp \left(-\lambda_{i t}\right)\right]\right. \\
& \left.+\left(\alpha N_{i t}-1\right) \log S_{i t}-\alpha \exp \left(-\lambda_{i t}\right) S_{i t}\right\} \\
& +\left(\alpha_{0}-1\right) \log \alpha-\beta_{0} \alpha
\end{aligned}
$$

where

$$
\lambda_{i t}=x_{i}^{T} \eta+d_{1, t}+d_{2, i}
$$

## D. Posterior mean with upper and lower multiplication factors

## D.1. Postal categories

Table D.1: Claim frequency for the postal categories with posterior mean, upper and lower multiplication factors and $95 \%$ posterior interval for the categories.

| Claim frequency |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Nr. code | Region | Mean | L.b.m.f | U.b.m.f | $95 \%$ lower | $95 \%$ upper |
| 1 | Reykjavík | 0,0743 | 0,8258 | 1,1868 | 0,0613 | 0,0882 |
| 2 | Reykjavík Urban Region | 0.0663 | 0.8435 | 1.1635 | 0.0560 | 0.0772 |

## E. Figures for claim frequency and expected compensation

E.1. Claim frequency

Figure E.1: Average claim frequency with $95 \%$ posterior interval for postal codes 101-116.

Figure E.D: Average claim frequency with $95 \%$ posterior interval for postal codes 170-225.

Figure E.3: Average claim frequency with $95 \%$ posterior interval for postal codes 230-270.

Figure E.4: Average claim frequency with $95 \%$ posterior interval for postal codes 300-380.

Figure E.5: Average claim frequency with $95 \%$ posterior interval for postal codes 400-471.

Figure E.6: Average claim frequency with $95 \%$ posterior interval for postal codes 500-566.

Figure E.7: Average claim frequency with $95 \%$ posterior interval for postal codes 570-630.

Figure E.8: Average claim frequency with $95 \%$ posterior interval for postal codes 640-690.

Figure E.9: Average claim frequency with $95 \%$ posterior interval for postal codes 700-785.

Figure E.10: Average claim frequency with $95 \%$ posterior interval for postal codes 800-900.

## E.2. Expected compensation

Figure E.11: Expected compensation with $95 \%$ posterior interval for postal codes 101-116.

Figure E.12: Expected compensation with 95\% posterior interval for postal codes 170-225.

Figure E.13: Expected compensation with $95 \%$ posterior interval for postal codes 230-270.

Figure E.14: Expected compensation with $95 \%$ posterior interval for postal codes 300-380.

Figure E.15: Expected compensation with $95 \%$ posterior interval for postal codes 400-471.

Figure E.16: Expected compensation with $95 \%$ posterior interval for postal codes 500-566.

Figure E.17: Expected compensation with $95 \%$ posterior interval for postal codes 570-630.

Figure E.18: Expected compensation with $95 \%$ posterior interval for postal codes 640-690.

Figure E.19: Expected compensation with $95 \%$ posterior interval for postal codes 700-785.

Figure E.20: Expected compensation with $95 \%$ posterior interval for postal codes 800-900.
