# Estimating Potential Merger Gains with Bilevel Programming DEA 

Haofei Wang

May 2011

#### Abstract

In today's economy and society, merger has a very important role in the restructuring of many sectors. In this thesis, we introduce an innovative Bilevel Programming Data Envelopment Analysis approach to evaluate the profit efficiency of the hierarchical system both pre-merger and post-merger. This hierarchical system consists of two levels, the Leader and the Follower, and the Leader is at the dominant level. A $\alpha$ -Strategy is proposed to stimulate the Follower to actively participate and stabilize the hierarchical structure. The potential gains from the merger are decomposed into harmony effect and scale effect. Two case studies are used to illustrate our proposed approach. The results show considerable potential gains from the promising mergers. The concept of coordinated effective merger is also discussed, and it is very important since every member in the system benefits from the merger.

## Chapter 1

## Introduction

Over the course of the past 30 years, attempts of consolidations in the form of merger and acquisition have greatly increased in competitive business environments and have attracted the attention of a growing number of financial economists. A lot of mergers and takeovers are reported in the business press. The shareholder value and operating performance can be improved by a merger in operating benefits such as economies of scale, asset restructuring, and technical and managerial skill transfer, financial benefits such as risk reduction, increased debt capacity and lower interest rates and tax savings (Rappaport, 1986).

From many empirical findings, the advantages of mergers have been verified. Hoffman and Weinberg (1998) report a case study that the Chemical Banking Corp and the Chase Manhattan Bank NA gained $\$ 1.5$ billion from cost saving after three years of a merger. Similarly, Murray (1997) states that owing to the merger First Union Core States bank achieved a $\$ 50$ million cost saving in updating banking information systems.

Gugler et al. (2003) identify that for large companies, mergers increase profits by increasing market power, whereas for small firms, mergers increase profits by increasing efficiency.

The basic analytical framework to investigate the merger is examining efficiency effect, financial ratios, econometric cost measures and the effect of the merger announcement on the stock of the acquiring and acquired firms. A number of studies evaluate the effects of the actual mergers.

A recent contribution is Bogetoft and Wang (2005). They estimate the potential gains from mergers and decompose the gains into two parts, one is called the harmony effect, the gains associated with reallocation among similarly sized firms, and the
other is called the scale effect, the gains that are available by changing the scale of the firms.

With the development of human society and the intensification of economic globalization, the scale of practical decision problems increases, meanwhile the structure of them becomes more and more complex. As one of the characters of system, hierarchy is very important when there are multiple players involved in the system, such as productive plans, resource distributions, engineering design problems etc.

Hierarchical decision problems have more than one decision maker, which have their own decision variables and objectives to optimize, also called multilevel programming problems. The Bilevel programming problem (BLP) is a special case of the multilevel programming problems with two levels in a hierarchy, the upper level and lower level decision makers. The decision maker at the upper level, which is also termed as the Leader, makes the choice first to optimize his objective. Knowing the decision of the Leader, the Follower makes his response which in turn affects the Leader's outcome.

Since the formal formulation of the linear BLP proposed by Candler and Townsley in 1982, many authors studied BLP intensively and contributed to this field. A lot of potential applications of BLP are presented by Dempe (2003), such as in the field of economics, engineering, ecology, transportation, game theory and so on.

Due to the hierarchical structure, the BLP is generically non-convex and non-differentiable and intrinsically hard to solve, even if the objective functions of the both levels and the constraints are all linear. The main existing methods for solving this problem are methods based on vertex enumeration, methods based on Kuhn-Tucker conditions, fuzzy approach and methods based on meta heuristics. The most popular among them is Kuhn-Tucker approach, and in this method, a one-level optimization problem is obtained by replacing the Follower's problem by the Kuhn-Tucker conditions. However, this method is proved to be deficient when the constraint functions of upper-level are in an arbitrary linear form and an extended Kuhn-Tucker approach was proposed by Shi et al. (2005) to overcome the deficiency of the original Kuhn-Tucker approach.

Many papers have been published on evaluating the operating efficiency using various approaches. To distinguish the best practice group among a set of observed units based on their inputs and outputs, and to indicate the differences between the inefficient units and the best practice group and improvements possible for the inefficient units, Data Envelopment Analysis (DEA) is by far the most used technique
( $\mathrm{Wu}, 2009$ ). This technique is flexible and powerful, and widely used in numerous empirical studies (Cooper et al.2000).

Based on the DEA technique, three types of the allocative efficiency can be identified when information on prices and costs are known exactly, cost efficiency, revenue efficiency and profit efficiency. Since considering the effects of the choice of vector of production on both costs and revenues, profit efficiency is a broader concept than the other two (Ariff and Can, 2007). In this thesis, we use the profit efficiency as the criteria to evaluate the operating performance.

Three existing studies, Wu (2010), Wu and Birge (2011), and Wu, Zhou and Birge (2010) have attributed much to this thesis. Wu (2010) creates innovative Bilevel programming DEA models to solve performance evaluation problem with the hierarchical structure using a cost-effective way. Based on this approach, the performance of both the system and the subsystem are exposed in details. Wu and Birge (2011) develop multi-stage series-chain merger DEA to evaluate merger efficiency and define merger efficiency concepts. A case illustration in a mortgage banking merger is given and significant gains from promising mergers of the mortgage banking chains are reported. In Wu, Zhou and Birge (2010), the merger efficiency is evaluated by a merger dynamic DEA model and using a comparison to stochastic frontier analysis, the utilization of DEA is validated. Our thesis is related to these three papers, but we apply the Bilevel programming DEA approach in the merger event.

In this thesis, we follow the DEA non-parametric approach and develop a DEA Bilevel programming model to evaluate the profit efficiency of above-mentioned hierarchical decision network structures before the merger and also after the merger. To encourage the Follower to participate in this hierarchical system, a $\alpha$-Strategy is suggested to strengthen the structure. With the completion of the merger, merger effect, harmony effect, and scale effect are derived and also used to measure the gain from the merger. The concept of coordinated effective merger is also discussed.

This thesis is outlined as follows. Chapter 2 gives a brief review of the Bilevel programming problem and DEA profit efficiency model. Chapter 3 develops Bilevel programming DEA to evaluate the profit efficiency. Chapter 4 proposes a methodology to evaluate the merger efficiency and decompose it into harmony effect and scale effect. Chapter 5 reports the empirical results from two numerical examples. Finally, conclusions, limitations and future research are presented in Chapter 6.

## Chapter 2

## Review of Bilevel programming problem and DEA profit efficiency

### 2.1 Bilevel programming problem

Bilevel programming problem is a hierarchical optimization problem consisting of two levels when the constraints of an optimization problem are also determined by the other optimization problem. The upper level, which is also termed as the Leader's level, is dominant over the lower level which is also considered as the Follower's level. The Leader makes the choice first to optimize his objective function. Observing the selection of the Leader, the Follower makes response which in turn affects the leader's outcome.

A Bilevel Linear Programming (BLP) given by Bard (1998) is formulated as follows:

$$
\begin{array}{ll}
\min _{x} & F(x, y)=p_{1}^{T} x+q_{1}^{T} y \\
\text { s.t. } & A_{1} x+B_{1} y \leq b_{1}  \tag{1}\\
\min _{y} & f(x, y)=p_{2}^{T} x+q_{2}^{T} y \\
\text { s.t. } & A_{2} x+B_{2} y \leq b_{2}
\end{array}
$$

where $x \in R^{n}, \quad y \in R^{m}$ refer to the decision variables corresponding to the upper and
lower level respectively, $p_{1}, p_{2} \in R^{n}, q_{1}, q_{2} \in R^{m}, b_{1} \in R^{c}, b_{2} \in R^{d}, A_{1} \in R^{c \times n}, B_{1} \in R^{c \times m}$, $A_{2} \in R^{d \times n}, B_{2} \in R^{d \times m}$ and T denotes transpose.

Let $u \in R^{p}, v \in R^{q}$ and $w \in R^{m}$ be the dual variables associated with the constraints $A_{1} x+B_{1} y \leq b_{1}, \quad A_{2} x+B_{2} y \leq b_{2}$ and $y \geq 0$, respectively. The following theorem is presented and proved by Shi et al. (2005) using an extended Kuhn-Tucker approach to reformulate Bilevel linear programming.

Theorem 1 (Shi et al., 2005) A necessary and sufficient condition that $\left(x^{*}, y^{*}\right)$ solves the BLP problem (1) is the existence of (row) vectors $u^{*}, v^{*}$ and $w^{*}$ such that $\left(x^{*}, y^{*}, u^{*}, v^{*}, w^{*}\right)$ solves the following Single level programming problem (2):

$$
\begin{array}{rl}
\min _{x, y, v, v, w} & F(x, y)=p_{1}^{T} x+q_{1}^{T} y \\
\text { s.t. } & A_{1} x+B_{1} y \leq b_{1}, \\
& A_{2} x+B_{2} y \leq b_{2},  \tag{2}\\
& u B_{1}^{T}+v B_{2}^{T}-w=-q_{2}, \\
& u^{T}\left(b_{1}-A_{1} x-B_{1} y\right)+v^{T}\left(b_{2}-A_{2} x-B_{2} y\right)+w^{T} y=0, \\
& x, y, u, v, w \geq 0 .
\end{array}
$$

Theorem 1 provides a method to transform the linear Bilevel programming problem into a single level programming problem which is a standard mathematical program and relatively easy to solve since all but one of the constraints are linear. And an extended branch and bound algorithm is proposed by Shi et al. (2006) to solve this model.

### 2.2 DEA profit efficiency

Data envelopment analysis (DEA) is a linear programming methodology to measure the efficiency of multiple organizations and indicate the differences between the inefficient ones and the best practice ones. DEA is a widely used technique to evaluate the performance of various organizations in public and private sectors.

In DEA, the organization is also called a decision making unit (DMU). Generically, a DMU is regarded as the entity responsible for converting inputs into outputs. For example, banks, supermarkets, car makers, hospitals etc can all be seen as DMUs.

Consider n DMUs that use a vector of p inputs: $x_{i}=\left(x_{i 1}, \ldots, x_{i p}\right)$ to produce a vector of
q outputs $y_{i}=\left(y_{i 1}, \ldots, y_{i q}\right)$. The profit efficiency for DMU j can be evaluated based on a linear programming model proposed by Cooper et al. (2000).

$$
\begin{array}{lll}
\max & \sum_{r=1}^{q} d_{r}{ }^{T} \tilde{y}_{j r}-\sum_{s=1}^{p} c_{s}{ }^{T} \tilde{x}_{j s} \\
\text { s.t. } & \sum_{i=1}^{n} \lambda_{i} x_{i r} \leq \tilde{x}_{j r} & (r=1, \ldots, p),  \tag{3}\\
& \sum_{i=1}^{n} \lambda_{i} y_{i s} \geq \tilde{y}_{j s} & (s=1, \ldots, q), \\
& \lambda_{i} \geq 0 & (i=1, \ldots, n),
\end{array}
$$

where $\left(\tilde{x}_{j 1}, \ldots, \tilde{x}_{j p}, \tilde{y}_{j 1}, \ldots, \tilde{y}_{j q}\right)$ are decision variables and $c=\left(c_{1}, \ldots, c_{p}\right)$ and $d=\left(d_{1}, \ldots, d_{q}\right)$ are the unit price vectors correlating to the input $\tilde{x}_{j}=\left(\tilde{x}_{j 1}, \ldots, \tilde{x}_{j p}\right)$ and output $\tilde{y}_{j=}\left(\tilde{y}_{j 1}, \ldots, \tilde{y}_{j q}\right)$ vectors respectively, $\lambda=\left(\lambda_{1}, \ldots, \lambda_{n}\right)$ is a nonnegative multiplier used to aggregate existing activities. The objective of Model (3) is to maximize the profit with the given prices of outputs $d$ and of inputs $c$. Based on an optimal solution $\left(x_{j 1}^{*}, \ldots, x_{j p}^{*}, y_{j 1}^{*}, \ldots, y_{j q}^{*}\right)$ of the above model, the profit efficiency of DMU j $\left(P E_{j}\right)$ is defined as follows:

$$
\begin{equation*}
P E_{j}=\frac{\sum_{r=1}^{q} d_{r} y_{j r}-\sum_{s=1}^{p} c_{s} x_{j s}}{\sum_{r=1}^{q} d_{r} y_{j r}^{*}-\sum_{s=1}^{p} c_{s} x_{j s}^{*}} \tag{4}
\end{equation*}
$$

where $y_{j}=\left(y_{j 1}, \ldots, y_{j q}\right), x_{j}=\left(x_{j 1}, \ldots, x_{j p}\right)$ are the vectors of observed values for DMU j .

Combining the demand and production of DMU $\mathrm{j},\left(P E_{j}\right)$ indicates the ratio between the observed profit and the optimized profit.

Under the assumption $\sum_{r=1}^{q} d_{r}^{T} y_{j r}-\sum_{s=1}^{p} c_{s}^{T} x_{j s}>0$, we have $0<P E_{j} \leq 1$, i.e. the profit efficiency score is within the range of 0 and 1 , and DMU $\mathrm{j}\left(x_{j}, y_{j}\right)$ is profit efficient if and only if $P E_{j}=1$.

## Chapter 3

## Bilevel programming DEA model

In this chapter, we combine the Bilevel programming and the DEA theory together to create Bilevel programming DEA models to evaluate the performance of the hierarchical system and the sub-levels based on the profit efficiency under two situations. The models are further reformulated in the standard linear Bilevel programming forms which can be easily transformed to the Single level programming problems according to Theorem 1 and solved by the extended branch and bound algorithms in Shi et al. (2006).

Suppose n Bilevel decision systems (DMUs) under evaluation, each indexed by j ( $j=$ $1,2, \ldots, n$ ) and each system (DMU) includes two decentralized subsystems: a Leader and a Follower. The Leader utilizes two types of inputs, i.e., the shared input $X^{1}$ and the possible direct input $X^{D 1}$, to produce two different types of outputs: the intermediate output $Y$ and the direct output $Z^{1}$. To produce the direct output $Z^{2}$, the Follower consumes three types of inputs, i.e., the shared input $X^{2}$ and the possible direct input $X^{D 2}$ and the intermediate input $Y$ from the Leader. The input is mostly constricted due to the limited resource in reality. In this case, the amount of the direct input and the total amount of the shared input are both upper bounded in this thesis. Fig. 1 depicts the framework of this Bilevel programming DEA model with limited resource.

Fig. 1. Bilevel programming DEA model with limited resource
Based on this hierarchical structure, we propose two situations.
In the first situation, we suppose that the Leader makes the decision based on his inputs (shared input $X^{1}$ and direct input $X^{D 1}$ ) and outputs (direct output $Z^{1}$ and intermediate output $Y$ ) first to maximize his own profit. Depending on the Leader's decision, the maximum resource available for the follower will be $X^{2}$ (or $E-X^{1}$ ) and $Y$ intermediate input. The Follower, based on his inputs (shared input $X^{2}$, direct input $X^{D 2}$ and intermediate input $Y$ ), determines the outputs (direct output $Z^{2}$ ) to maximize his profit.

The following model represents the case discussed above.
Model (5)

$$
\begin{aligned}
& \text { (P1) } \max _{\tilde{X}_{J}, \tilde{X}_{J}^{D T}, \tilde{Y}_{j}, \tilde{Z}_{J}^{\prime}, 2}\left(Q^{1^{T}} \tilde{Z}_{J}^{1}+Q^{2^{T}} \tilde{Y}_{J}^{1}\right)-\left(P^{1^{T}} \tilde{X}_{J}^{1}+P^{2^{T}} \tilde{X}_{J}^{D 1}\right) \\
& \text { s.t } \quad \tilde{X}_{J}^{1}+\tilde{X}_{J}^{2} \geq \sum_{j=1}^{n} X_{j}^{1} \lambda_{j}+\sum_{j=1}^{n} X_{j}^{2} \pi_{j}, \\
& \tilde{X}_{J}^{D 1} \geq \sum_{j=1}^{n} X_{j}^{D 1} \lambda_{j}, \\
& \quad \tilde{Z}_{J}^{1} \leq \sum_{j=1}^{n} Z_{j}^{1} \lambda_{j}, \\
& \quad \tilde{Y}_{J}^{1} \leq \sum_{j=1}^{n} Y_{j} \lambda_{j}, \\
& \quad \tilde{X}_{J}^{1}+\tilde{X}_{J}^{2} \leq E(\text { const. }), \\
& \tilde{X}_{J}^{D 1} \leq X_{J}^{D 1}, \\
& \\
& \left(Q^{1^{T}} \tilde{Z}_{J}^{1}+Q^{2^{T}} \tilde{Y}_{J}^{1}\right)-\left(P^{1^{T}} \tilde{X}_{J}^{1}+P^{2^{T}} \tilde{X}_{J}^{D 1}\right) \geq\left(Q^{1^{T}} Z_{J}^{1}+Q^{2^{T}} Y_{J}^{1}\right)-\left(P^{1^{T}} X_{J}^{1}+P^{2^{T}} X_{J}^{D 1}\right)
\end{aligned}
$$

$$
\begin{align*}
& \text { (P2) } \max _{\tilde{X}_{J}^{2}, \tilde{X}_{J}^{D}, \tilde{Y}_{J}^{2}, \tilde{Z}_{j}^{2}, \pi} Q^{3^{T}} \tilde{Z}_{J}^{2}-\left(P^{1^{T}} \tilde{X}_{J}^{2}+P^{3^{T}} \tilde{X}_{J}^{D^{2}}+Q^{2^{T}} \tilde{Y}_{J}^{2}\right)  \tag{5}\\
& \text { s.t } \quad \tilde{X}_{J}^{D 2} \geq \sum_{j=1}^{n} X_{j}^{D 2} \pi_{j}, \\
& \tilde{Y}_{J}^{2} \geq \sum_{j=1}^{n} Y_{j} \pi_{j}, \\
& \tilde{Z}_{J}^{2} \leq \sum_{j=1}^{n} Z_{j}^{2} \pi_{j}, \\
& \tilde{X}_{J}^{D 2} \leq X_{J}^{D 2}, \\
& \tilde{Y}_{J}^{2} \leq \tilde{Y}_{J}^{1}, \\
& Q^{3^{T}} \tilde{Z}_{J}^{2}-\left(P^{1^{T}} \tilde{X}_{J}^{2}+P^{3^{T}} \tilde{X}_{J}^{D 2}+Q^{2^{T}} \tilde{Y}_{J}^{2}\right) \geq Q^{3^{T}} Z_{J}^{2}-\left(P^{T^{T}} X_{J}^{2}+P^{3^{T}} X_{J}^{D 2}+Q^{2^{T}} Y_{J}^{2}\right) \\
& \tilde{X}_{J}^{1}, \tilde{X}_{J}^{2}, \tilde{X}_{J}^{D 1}, \tilde{X}_{J}^{D 2}, \tilde{Y}_{J}^{1}, \tilde{Y}_{J}^{2}, \tilde{Z}_{J}^{1}, \tilde{Z}_{J}^{2}, \lambda, \pi \geq 0
\end{align*}
$$

where T denotes transpose, $Y^{1}$ denotes the intermediate output from the Leader, $Y^{2}$ denotes the intermediate input consumed by the Follower, $P^{1}$ is the unit cost vector of the shared inputs $X^{1}, X^{2}$ to the Leader and the Follower, $P^{2}, P^{3}$ are the unit cost vectors correlating to the direct inputs $X^{D 1}, X^{D 2}$ to the Leader and the Follower. $Q^{1}$, $Q^{3}$ are the unit price vectors of the Leader's direct output $Z^{1}$ and the Follower's direct output $Z^{2}$, respectively. $Q^{2}$ is the unit price vector both of the Leader's intermediate output $Y^{1}$ and the Follower's intermediate input $Y^{2}$.

Model (5) is characterized as a constant returns-to-scale (CRS) DEA model, which is noted in Cooper et al. (2000). Returns-to-scale refers to changes in output resulting from a proportional change in all inputs. CRS reflects the fact that outputs will change by the same proportion as inputs are changed. If we add the constraints $\sum_{i=1}^{n} \lambda_{i}=1$, $\sum_{i=1}^{n} \pi_{i}=1$ respectively, in the upper level and lower level in Model (5), we will have the variable returns-to-scale (VRS) DEA model. VRS reflects the fact that production technology may exhibit increasing, constant and decreasing returns-to-scale. Increasing returns-to-scale means outputs increase by more than that proportional change in all inputs, however decreasing returns-to-scale means outputs increase by less than that proportional change in all inputs.

Model (5) can be reformulated in the standard linear Bilevel programming form as shown in Appendix I.

According to Theorem 1, the corresponding Single level problem can be obtained. The variables and coefficient matrixes in the Single level problem are shown in Appendix I.

In the second situation, we swap the position of the Leader and the Follower. The new Leader, who is the Follower in the first situation, maximizes his profit by choosing the inputs (shared input $X^{2}$, direct input $X^{D 2}$ and intermediate input $Y$ ) and outputs (direct output $Z^{2}$ ). After the intermediate input $Y$ is determined by the new Leader, the minimum intermediate output required from the new Follower will be $Y$. The new Follower determines on his inputs (shared input $X^{1}$ and direct input $X^{D 1}$ ) and outputs (direct output $Z^{1}$ and intermediate output $Y$ ) to maximize his profit then. Fig. 2 and the Model (6) depict the case discussed above.

Fig. 2. Bilevel programming DEA model with limited resource in the $2^{\text {nd }}$ situation

Model (6)

$$
\begin{aligned}
& \text { (Pl) } \max _{\tilde{X}_{J}^{2}, \tilde{X}_{J}^{D}, \tilde{Z}_{J}^{2}, \tilde{Y}_{J}^{2}, \pi} P^{2^{T}} \tilde{Z}_{J}^{2}-\left(C^{1^{T}} \tilde{X}_{J}^{2}+C^{3^{T}} \tilde{X}_{J}^{D^{2}}+Q^{T} \tilde{Y}_{J}^{2}\right) \\
& \text { s.t } \quad \tilde{X}_{J}^{2}+\tilde{X}_{J}^{1} \geq \sum_{j=1}^{n} X_{j}^{2} \pi_{j}+\sum_{j=1}^{n} X_{j}^{1} \lambda_{j}, \\
& \tilde{X}_{J}^{D 2} \geq \sum_{j=1}^{n} X_{j}^{D 2} \pi_{j}, \\
& \tilde{Y}_{J}^{2} \geq \sum_{j=1}^{n} Y_{j} \pi_{j}, \\
& \tilde{Z}_{J}^{2} \leq \sum_{j=1}^{n} Z_{j}^{2} \pi_{j}, \\
& \tilde{X}_{J}^{D 2} \leq X_{J}^{D 2}, \\
& \tilde{X}_{J}^{1}+\tilde{X}_{J}^{2} \leq E \text { (const.), } \\
& P^{2^{T}} \tilde{Z}_{J}^{2}-\left(C^{1^{T}} \tilde{X}_{J}^{2}+C^{3^{T}} \tilde{X}_{J}^{D 2}+Q^{T} \tilde{Y}_{J}^{2}\right) \geq P^{2^{T}} Z_{J}^{2}-\left(C^{1^{T}} X_{J}^{2}+C^{3^{T}} X_{J}^{D 2}+Q^{T} Y_{J}^{2}\right),
\end{aligned}
$$

$$
\begin{align*}
& (P 2) \max _{\tilde{X}_{,}^{\prime}, \tilde{X}_{J}^{D}, \bar{Y}_{1}^{\prime}, \tilde{Z}_{J}^{1}, \lambda}\left(P^{1^{T}} \tilde{Z}_{J}^{1}+Q^{T} \tilde{Y}_{J}^{1}\right)-\left(C^{1^{T}} \tilde{X}_{J}^{1}+C^{2^{T}} \tilde{X}_{J}^{D 1}\right)  \tag{6}\\
& \text { s.t } \quad \tilde{X}_{J}^{D 1} \geq \sum_{j=1}^{n} X_{j}^{D 1} \lambda_{j}, \\

& \quad \tilde{Y}_{J}^{1} \geq \tilde{Y}_{J}^{2}, \\
& \\
& \left(P^{T} \tilde{Z}_{J}^{1}+Q^{T} \tilde{Y}_{J}^{1}\right)-\left(C^{1^{T}} \tilde{X}_{J}^{1}+C^{2^{T}} \tilde{X}_{J}^{D 1}\right) \geq\left(P^{1^{T}} Z_{J}^{1}+Q^{T} Y_{J}^{1}\right)-\left(C^{1^{T}} X_{J}^{1}+C^{2^{T}} X_{J}^{D 1}\right) \\
& \\
& \tilde{X}_{J}^{1}, \tilde{X}_{J}^{2}, \tilde{X}_{J}^{D 1}, \tilde{X}_{J}^{D 2}, \tilde{Y}_{J}^{1}, \tilde{Y}_{J}^{2}, \tilde{Z}_{J}^{1}, \tilde{Z}_{J}^{2}, \lambda, \pi \geq 0
\end{align*}
$$

where the notations are also the same with those in Model (5).
The standard linear Bilevel programming form of Model (6) is shown in Appendix I.
Similarly to the first two situations, the corresponding Single level problem can be obtained according to Theorem 1. The variables and coefficient matrixes in the Single level problem are shown in Appendix I.

The following definitions about the profit efficiency are used to evaluate the performance of the two levels as well as the whole system.

Definition 1(Profit efficiency of the $\mathrm{I}^{\text {th }}$ Leader)
The profit efficiency of the $\mathrm{I}^{\text {th }}$ Leader in the first situation is defined as

$$
\begin{equation*}
P E_{I}^{L}=\frac{\left(Q^{1^{T}} Z_{I}^{1}+Q^{2^{T}} Y_{I}^{1}\right)-\left(P^{1^{T}} X_{I}^{1}+P^{2^{T}} X_{I}^{D 1}\right)}{\left(Q^{1^{T}} Z_{I}^{l^{*}}+Q^{2^{T}} Y_{I}^{1^{*}}\right)-\left(P^{1^{T}} X_{I}^{1^{*}}+P^{2^{T}} X_{I}^{D 1^{*}}\right)}, \tag{7}
\end{equation*}
$$

where $X_{I}^{1^{*}}, X_{I}^{D 1^{*}}, Y_{I}^{*}, Z_{I}^{1^{*}}$ are the optimal solutions to Model (5).

The $I^{\text {th }}$ Leader is termed profit efficient if and only if the profit efficiency of the $I^{\text {th }}$ Leader is 1 , i.e. $P E_{I}^{L}=1$.

Definition 2(Profit efficiency of the $I^{\text {th }}$ Follower)
The profit efficiency of the $I^{\text {th }}$ Follower in the first situation is defined as

$$
\begin{equation*}
P E_{I}^{F}=\frac{Q^{3^{T}} Z_{I}^{2}-\left(P^{1^{T}} X_{I}^{2}+P^{3^{T}} X_{I}^{D 2}+Q^{2^{T}} Y_{I}^{2}\right)}{Q^{3^{T}} Z_{I}^{2^{*}}-\left(P^{1^{T}} X_{I}^{2^{*}}+P^{3^{T}} X_{I}^{D 2^{*}}+Q^{2^{T}} Y_{I}^{2^{*}}\right)}, \tag{8}
\end{equation*}
$$

where $Z_{I}^{2^{*}}, X_{I}^{2^{*}}, X_{I}^{D 2^{*}}, Y_{I}^{*}$ are the optimal solutions to Model (5).

The $\mathrm{I}^{\text {th }}$ Follower is termed profit efficient if and only if the profit efficiency of the $\mathrm{I}^{\text {th }}$ Follower is 1, i.e. $P E_{I}^{F}=1$.

Definition 3(Profit efficiency of the $\mathrm{I}^{\text {th }}$ system)
The profit efficiency of the $\mathrm{I}^{\text {th }}$ system in the first situation is defined as

$$
\begin{equation*}
P E_{I}^{S}=\frac{\left(Q^{1^{T}} Z_{I}^{1}+Q^{2^{T}} Y_{I}^{1}+Q^{3^{T}} Z_{I}^{2}\right)-\left(P^{1^{T}} X_{I}^{1}+P^{2^{T}} X_{I}^{D 1}+P^{1^{T}} X_{I}^{2}+P^{3^{T}} X_{I}^{D 2}+Q^{2^{T}} Y_{I}^{2}\right)}{\left(Q^{1^{T}} Z_{I}^{I^{*}}+Q^{2^{T}} Y_{I}^{i^{*}}+Q^{3^{T}} Z_{I}^{2^{*}}\right)-\left(P^{I^{T}} X_{I}^{1^{*}}+P^{2^{T}} X_{I}^{D 1^{*}}+P^{1^{T}} X_{I}^{2^{*}}+P^{3^{T}} X_{I}^{D 2^{*}}+Q^{2^{T}} Y_{I}^{2^{*}}\right)} \tag{9}
\end{equation*}
$$

where $X_{I}^{1^{*}}, X_{I}^{2^{*}}, X_{I}^{D 1^{*}}, X_{I}^{D 2^{*}}, Y_{I}^{1^{*}}, Y_{I}^{2^{*}}, Z_{I}^{1^{*}}, Z_{I}^{2^{*}}$ are the optimal solutions to Model (5).

The $I^{\text {th }}$ system is termed profit efficient if and only if the profit efficiency of the $\mathrm{I}^{\text {th }}$ system is 1, i.e. $P E_{I}^{S}=1$.

Similarly, the profit efficiency of the Leader, the Follower and the whole system can be defined in the second situation.

Under the assumption that the actual profit is positive, we present the following three propositions about the profit efficiency of the Leader, the Follower and the system under both of these two situations. The first and the third propositions are similar to the propositions about the cost efficiency in Wu (2010).

## Proposition 1

In the $I^{\text {th }}$ system, if the profit efficiency of the Leader $P E_{I}^{L}$ is greater than that of the Follower $P E_{I}^{F}$, then $P E_{I}^{L}>P E_{I}^{S}>P E_{I}^{F}$; if the profit efficiency of the Leader $P E_{I}^{L}$ equals that of the Follower $P E_{I}^{F}$, then $P E_{I}^{L}=P E_{I}^{S}=P E_{I}^{F}$; if the profit efficiency of the Leader $P E_{I}^{L}$ is less than that of the Follower $P E_{I}^{F}$, then $P E_{I}^{L}<P E_{I}^{S}<P E_{I}^{F}$.

## Proof

Similar to the proof of Proposition 1 in Wu (2010).

## Proposition 2

In the $\mathrm{I}^{\text {th }}$ system, the profit efficiency of the whole system $P E_{I}^{S}$, which is the system performance measure, is a convex combination of the profit efficiency of the Leader $P E_{I}^{L}$ and profit efficiency of the Follower $P E_{I}^{F}$.

Proof
Let $\omega_{1}=\frac{\left(P^{1^{T}} Z_{I}^{1^{*}}+Q^{T} Y_{I}^{1^{*}}\right)-\left(C^{1^{T}} X_{I}^{1^{*}}+C^{2^{T}} X_{I}^{D 1^{*}}\right)}{\left(P^{I^{T}} Z_{I}^{1^{*}}+Q^{T} Y_{I}^{1^{*}}+P^{2^{T}} Z_{I}^{2^{*}}\right)-\left(C^{1^{T}} X_{I}^{1^{*}}+C^{2^{T}} X_{I}^{D 1^{*}}+C^{I^{T}} X_{I}^{2^{*}}+C^{3^{T}} X_{I}^{D 2^{*}}+Q^{T} Y_{I}^{2^{*}}\right)}$
and $\omega_{2}=\frac{2^{2^{T}} Z_{I}^{2^{*}}-\left(C^{1^{T}} X_{I}^{2^{*}}+C^{3^{T}} X_{I}^{D 2^{*}}+Q^{T} Y_{I}^{2^{*}}\right)}{\left(P^{1^{T}} Z_{I}^{1^{*}}+Q^{T} Y_{I}^{1^{*}}+P^{2^{T}} Z_{I}^{2^{*}}\right)-\left(C^{1^{T}} X_{I}^{1^{*}}+C^{2^{T}} X_{I}^{D 1^{*}}+C^{1^{T}} X_{I}^{2^{*}}+C^{3^{T}} X_{I}^{D 2^{*}}+Q^{T} Y_{I}^{2^{*}}\right)} ;$
then, it is easy to see $\omega_{1}+\omega_{2}=1$ and $P E_{I}^{S}=\omega_{1} P E_{I}^{L}+\omega_{2} P E_{I}^{F}$, which complete the proof.

## Proposition 3

In the $\mathrm{I}^{\text {th }}$ system, the system is efficient, i.e. $P E_{I}^{S}=1$, only if both of the Leader and the Follower are efficient, i.e. $P E_{I}^{L}=1$ and $P E_{I}^{F}=1$.

## Proof

Similar to the proof of Proposition 2 in Wu (2010).

## Chapter 4

## The evaluation of the merger

## efficiency

In order to analyze the potential gains from the merger of N Bilevel systems, and evaluate the merger efficiency, the following steps are proposed (Wu and Birge, 2011) and the first situation is used to set an example.

Step 1: First solve the Bilevel programming problem for each DMU using Model (5). According to Theorem 1 and the branch and bound algorithm, we can obtain the optimal solution of $\left(X_{J}^{1^{*}}, X_{J}^{2^{*}}, X_{J}^{D D^{*}}, X_{J}^{D 2^{*}}, Y_{J}^{i^{*}}, Y_{J}^{2^{*}}, Z_{J}^{1^{*}}, Z_{J}^{2^{*}}, \lambda^{*}, \pi^{*}\right)$, and it is an optimal production decision for each DMU to be efficient. We then construct the efficient input-output combination ( $X_{J}^{1^{*}}, X_{J}^{2^{*}}, X_{J}^{D 1^{*}}, X_{J}^{D 2^{*}}, Y_{J}^{1^{*}}, Y_{J}^{2^{*}}, Z_{J}^{1^{*}}, Z_{J}^{2^{*}}$ ) for each Bilevel system.

Step 2: Compute the average input bundle, intermediate output/input bundle and out bundle

$$
\begin{aligned}
\bar{X}^{1} & =\frac{1}{n} \sum_{j=1}^{n} X_{j}^{1^{*}}, \\
\bar{X}^{2} & =\frac{1}{n} \sum_{j=1}^{n} X_{j}^{2^{*}}, \\
\bar{X}^{D 1} & =\frac{1}{n} \sum_{j=1}^{n} X_{j}^{D 1^{*}}, \\
\bar{X}^{D 2} & =\frac{1}{n} \sum_{j=1}^{n} X_{j}^{D 2^{*}}, \\
\bar{Y}^{1} & =\frac{1}{n} \sum_{j=1}^{n} Y_{j}^{1^{*}},
\end{aligned}
$$

$$
\begin{aligned}
\bar{Y}^{2} & =\frac{1}{n} \sum_{j=1}^{n} Y_{j}^{2^{*}}, \\
\bar{Z}^{1} & =\frac{1}{n} \sum_{j=1}^{n} Z_{j}^{1^{*}}, \\
\bar{Z}^{2} & =\frac{1}{n} \sum_{j=1}^{n} Z_{j}^{2^{*}},
\end{aligned}
$$

Step 3: Solve the Bilevel programming DEA problem with the average input bundle Model (10)

$$
\begin{align*}
& (P 1) \max _{X_{H}^{1}, X_{H}^{D}, Z_{H}^{1}, Y_{H}^{1}, \lambda}\left(Q^{1^{T}} Z_{H}^{1}+Q^{2^{T}} Y_{H}^{1}\right)-\left(P^{T^{T}} X_{H}^{1}+P^{2^{T}} X_{H}^{D 1}\right) \\
& \text { s.t } \quad X_{H}^{1}+X_{H}^{2} \geq \sum_{j=1}^{n} X_{j}^{1} \lambda_{j}+\sum_{j=1}^{n} X_{j}^{2} \pi_{j}, \\
& X_{H}^{D 1} \geq \sum_{j=1}^{n} X_{j}^{D 1} \lambda_{j}, \\
& Z_{H}^{1} \leq \sum_{j=1}^{n} Z_{j}^{1} \lambda_{j}, \\
& Y_{H}^{1} \leq \sum_{j=1}^{n} Y_{j} \lambda_{j}, \\
& X_{H}^{1}+X_{H}^{2} \leq E(\text { const. }), \\
& X_{H}^{D 1} \leq \bar{X}^{D 1} \text {, } \\
& \text { (P2) } \max _{X_{H}^{2}, X_{H}^{D 2}, Y_{H}^{2}, Z_{H}^{2}, \pi^{2}} Q^{3^{T}} Z_{H}^{2}-\left(P^{1^{T}} X_{H}^{2}+P^{3^{T}} X_{H}^{D 2}+Q^{2^{T}} Y_{H}^{2}\right)  \tag{10}\\
& \text { s.t } \quad X_{H}^{D 2} \geq \sum_{j=1}^{n} X_{j}^{D 2} \pi_{j}, \\
& Y_{H}^{2} \geq \sum_{j=1}^{n} Y_{j} \pi_{j}, \\
& Z_{H}^{2} \leq \sum_{j=1}^{n} Z_{j}^{2} \pi_{j}, \\
& X_{H}^{D 2} \leq \bar{X}^{D 2}, \\
& Y_{H}^{2} \leq Y_{H}^{1}, \\
& X_{H}^{1}, X_{H}^{2}, X_{H}^{D 1}, X_{H}^{D 2}, Y_{H}^{1}, Y_{H}^{2}, Z_{H}^{1}, Z_{H}^{2}, \lambda_{H}, \pi_{H} \geq 0
\end{align*}
$$

Model (10) can be reformulated in a standard Bilevel programming form which can be easily transformed to the Single programming problem, as shown in Appendix I.

The variables and coefficient matrixes in the Single level problem corresponding to Model (10) are shown in Appendix I.

The Single programming problem can be solved by branch and bound algorithms
mentioned before. Denote by $\left(X_{H}^{1^{*}}, X_{H}^{2^{*}}, X_{H}^{D 1^{*}}, X_{H}^{D 2^{*}}, Y_{H}^{1^{*}}, Y_{H}^{2^{*}}, Z_{H}^{1^{*}}, Z_{H}^{2^{*}}, \lambda_{H}^{*}, \pi_{H}^{*}\right)$ the optimal solution to Model (10), and it is an optimal production decision for the individual DMU using the average input bundle before merger.

Step 4: Define the total (slack-adjusted) input and output bundles of N systems

$$
\begin{aligned}
X_{\text {Total }}^{1} & =N \cdot \bar{X}^{1}, \\
X_{\text {Total }}^{2} & =N \cdot \bar{X}^{2}, \\
X_{\text {Total }}^{D 1} & =N \cdot \bar{X}^{D 1}, \\
X_{\text {Total }}^{D 2} & =N \cdot \bar{X}^{D 2}, \\
Y_{\text {Total }}^{1} & =N \cdot \bar{Y}^{1}, \\
Y_{\text {Total }}^{2} & =N \cdot \bar{Y}^{2}, \\
Z_{\text {Total }}^{1} & =N \cdot \bar{Z}^{1}, \\
Z_{\text {Total }}^{2} & =N \cdot \bar{Z}^{2} .
\end{aligned}
$$

Step 5: Solve the Bilevel programming merger DEA problem

## Model (11)

$$
\begin{gather*}
(P 1) \max _{X_{M}^{1}, X_{M}^{1}, Z_{M}^{1}, Y_{M}^{1}, \lambda}\left(Q^{1^{T}} Z_{M}^{1}+Q^{2^{T}} Y_{M}^{1}\right)-\left(P^{1^{T}} X_{M}^{1}+P^{2^{T}} X_{M}^{D 1}\right) \\
\text { s.t } \quad X_{M}^{1}+X_{M}^{2} \geq \sum_{j=1}^{n} X_{j}^{1} \lambda_{j}+\sum_{j=1}^{n} X_{j}^{2} \pi_{j}, \\
X_{M}^{D 1} \geq \sum_{j=1}^{n} X_{j}^{D 1} \lambda_{j}, \\
Z_{M}^{1} \leq \sum_{j=1}^{n} Z_{j}^{1} \lambda_{j}, \\
Y_{M}^{1} \leq \sum_{j=1}^{n} Y_{j} \lambda_{j}, \\
X_{M}^{1}+X_{M}^{2} \leq N \cdot E(\text { const. }), \\
\\
X_{M}^{D 1} \leq X_{T o t a l}^{D 1},  \tag{11}\\
\text { (P2) } \max _{X_{M}^{2}, X_{M}^{D 2}, Z_{M}^{2}, Y_{M}^{2}, \pi}^{Q^{3^{T}}} Z_{M}^{2}-\left(P^{1^{T}} X_{M}^{2}+P^{3^{T}} X_{M}^{D 2}+Q^{2^{T}} Y_{M}^{2}\right) \\
\text { s.t } \quad X_{M}^{D 2} \geq \sum_{j=1}^{n} X_{j}^{D 2} \pi_{j}, \\
Y_{M}^{2} \geq \sum_{j=1}^{n} Y_{j} \pi_{j}, \\
Z_{M}^{2} \leq \sum_{j=1}^{n} Z_{j}^{2} \pi_{j},
\end{gather*}
$$

$$
\begin{aligned}
& X_{M}^{D 2} \leq X_{\text {Total }}^{D 2}, \\
& Y_{M}^{2} \leq Y_{M}^{1}, \\
& X_{M}^{1}, X_{M}^{2}, X_{M}^{D 1}, X_{M}^{D 2}, Y_{M}^{1}, Y_{M}^{2}, Z_{M}^{1}, Z_{M}^{2}, \lambda_{M}, \pi_{M} \geq 0
\end{aligned}
$$

Model (11) can be also reformulated in a standard Bilevel programming form which can be easily transformed to the Single programming problem, shown in Appendix I.

The variables and coefficient matrixes in the Single level problem corresponding to Model (11) are shown in Appendix I.

Then the Single programming problem can be solved. Denote by $\left(X_{M}^{1^{*}}, X_{M}^{2^{*}}, X_{M}^{D 1^{*}}, X_{M}^{D 2^{*}}, Y_{M}^{1^{*}}, Y_{M}^{2^{*}}, Z_{M}^{1^{*}}, Z_{M}^{2^{*}}, \lambda_{M}^{*}, \pi_{M}^{*}\right)$ the optimal solution to Model (11), and it is an optimal production decision for the merger involved DMUs after merger.

## Proposition 4

Under the constant returns to scale (CRS) assumption, the optimal solution to Model
(11) $\left(X_{M}^{1^{*}}, X_{M}^{2^{*}}, X_{M}^{D 1^{*}}, X_{M}^{D 2^{*}}, Y_{M}^{1^{*}}, Y_{M}^{2^{*}}, Z_{M}^{1^{*}}, Z_{M}^{2^{*}}, \lambda_{M}^{*}, \pi_{M}^{*}\right)$ is N multiple of the optimal solution to $\operatorname{Model}(10)\left(X_{H}^{1^{*}}, X_{H}^{2^{*}}, X_{H}^{D 1^{*}}, X_{H}^{D 2^{*}}, Y_{H}^{1^{*}}, Y_{H}^{2^{*}}, Z_{H}^{1^{*}}, Z_{H}^{2^{*}}, \lambda_{H}^{*}, \pi_{H}^{*}\right)$.

## Proof

Multiply both of the object functions and both sides of all the constraints in Model (10) by N, and define this new model by Model (12).

Model (12)

$$
\begin{aligned}
& (P 1) \max _{X_{H}^{1}, X_{H}^{1}, Z_{H}^{1}, Y_{H}^{1}, \lambda} N \cdot\left[\left(Q^{1^{T}} Z_{H}^{1}+Q^{2^{T}} Y_{H}^{1}\right)-\left(P^{1^{T}} X_{H}^{1}+P^{2^{T}} X_{H}^{D 1}\right)\right] \\
& \text { s.t } \quad \mathrm{N} \cdot\left(X_{H}^{1}+X_{H}^{2}\right) \geq N \cdot\left(\sum_{j=1}^{n} X_{j}^{1} \lambda_{j}+\sum_{j=1}^{n} X_{j}^{2} \pi_{j}\right), \\
& \mathrm{N} \cdot X_{H}^{D 1} \geq \mathrm{N} \cdot \sum_{j=1}^{n} X_{j}^{D 1} \lambda_{j}, \\
& \mathrm{~N} \cdot Z_{H}^{1} \leq \mathrm{N} \cdot \sum_{j=1}^{n} Z_{j}^{1} \lambda_{j}, \\
& \mathrm{~N} \cdot Y_{H}^{1} \leq \mathrm{N} \cdot \sum_{j=1}^{n} Y_{j} \lambda_{j}, \\
& \mathrm{~N} \cdot\left(X_{H}^{1}+X_{H}^{2}\right) \leq \mathrm{N} \cdot E \\
& \mathrm{~N} \cdot X_{H}^{D 1} \leq \mathrm{N} \cdot \bar{X}^{D 1},
\end{aligned}
$$

$$
\begin{gather*}
\text { (P2) } \max _{X_{H}^{2}, X_{H}^{D}, Y_{H}^{2}, Z_{H}^{2}, \pi^{2}} \mathrm{~N} \cdot\left[Q^{3^{T}} Z_{H}^{2}-\left(P^{1^{T}} X_{H}^{2}+P^{3^{T}} X_{H}^{D 2}+Q^{2^{T}} Y_{H}^{2}\right)\right]  \tag{12}\\
\text { s.t } \quad \mathrm{N} \cdot X_{H}^{D 2} \geq \mathrm{N} \cdot \sum_{j=1}^{n} X_{j}^{D 2} \pi_{j}, \\
\mathrm{~N} \cdot Y_{H}^{2} \geq \mathrm{N} \cdot \sum_{j=1}^{n} Y_{j} \pi_{j}, \\
\mathrm{~N} \cdot Z_{H}^{2} \leq \mathrm{N} \cdot \sum_{j=1}^{n} Z_{j}^{2} \pi_{j}, \\
\mathrm{~N} \cdot X_{H}^{D 2} \leq \mathrm{N} \cdot \bar{X}^{D 2}, \\
\mathrm{~N} \cdot Y_{H}^{2} \leq \mathrm{N} \cdot Y_{H}^{1}, \\
\\
X_{H}^{1}, X_{H}^{2}, X_{H}^{D 1}, X_{H}^{D 2}, Y_{H}^{1}, Y_{H}^{2}, Z_{H}^{1}, Z_{H}^{2}, \lambda_{H}, \pi_{H} \geq 0
\end{gather*}
$$

Define new variables that are equal to N times of those in Model (12).

$$
\begin{aligned}
\tilde{X}_{H}^{1} & =N \cdot X_{H}^{1}, \\
\tilde{X}_{H}^{2} & =N \cdot X_{H}^{2}, \\
\tilde{X}_{H}^{D 1} & =N \cdot X_{H}^{D 1}, \\
\tilde{X}_{H}^{D 2} & =N \cdot X_{H}^{D 2}, \\
\tilde{Y}_{H}^{1} & =N \cdot Y_{H}^{1}, \\
\tilde{Y}_{H}^{2} & =N \cdot Y_{H}^{2}, \\
\tilde{Z}_{H}^{1} & =N \cdot Z_{H}^{1}, \\
\tilde{Z}_{H}^{2} & =N \cdot Z_{H}^{2}, \\
\tilde{\lambda}_{H} & =N \cdot \lambda_{H}, \\
\tilde{\pi}_{H} & =N \cdot \pi_{H}
\end{aligned}
$$

Then the adjusted Model (12) is shown as follows.

$$
\begin{aligned}
& (P 1) \max _{\tilde{X}_{H}^{1}, \bar{X}_{H}^{D}, \bar{Z}_{H}^{1}, \tilde{Y}_{H}, \tilde{\tau}}\left(Q^{1^{T}} \tilde{Z}_{H}^{1}+Q^{2^{T}} \tilde{Y}_{H}^{1}\right)-\left(P^{1^{T}} \tilde{X}_{H}^{1}+P^{2^{T}} \tilde{X}_{H}^{D 1}\right) \\
& \text { s.t } \quad \tilde{X}_{H}^{1}+\tilde{X}_{H}^{2} \geq \sum_{j=1}^{n} X_{j}^{1} \tilde{\lambda}_{j}+\sum_{j=1}^{n} X_{j}^{2} \tilde{\pi}_{j} \\
& \tilde{X}_{H}^{D 1} \geq \sum_{j=1}^{n} X_{j}^{D 1} \tilde{\lambda}_{j} \\
& \tilde{X}_{H}^{1} \leq \sum_{j=1}^{n} Z_{j}^{1} \tilde{\lambda}_{j} \\
& \tilde{Y}_{H}^{1} \leq \sum_{j=1}^{n} Y_{j} \tilde{\lambda}_{j} \\
& \tilde{X}_{H}^{1}+\tilde{X}_{H}^{2} \leq N \cdot E \\
& \tilde{X}_{H}^{D 1} \leq N \cdot \bar{X}^{D 1}
\end{aligned}
$$

$$
\begin{align*}
& \text { (P2) } \max _{\tilde{X}_{H}^{2}, \tilde{X}_{H}^{D 2}, \mathcal{P}_{H}, \tilde{Z}_{H}^{2}, \tilde{\pi}} Q^{3^{T}} \tilde{Z}_{H}^{2}-\left(P^{1^{T}} \tilde{X}_{H}^{2}+P^{3^{T}} \tilde{X}_{H}^{D 2}+Q^{2^{T}} \tilde{Y}_{H}^{2}\right)  \tag{13}\\
& \text { s.t } \quad \tilde{X}_{H}^{D 2} \geq \sum_{j=1}^{n} X_{j}^{D 2} \tilde{\pi}_{j}, \\
& \tilde{Y}_{H}^{2} \geq \sum_{j=1}^{n} Y_{j} \tilde{\pi}_{j}, \\
& \quad \tilde{Z}_{H}^{2} \leq \sum_{j=1}^{n} Z_{j}^{2} \tilde{\pi}_{j}, \\
& \quad \tilde{X}_{H}^{D 2} \leq N \cdot \bar{X}^{D 2}, \\
& \tilde{Y}_{H}^{2} \leq \tilde{Y}_{H}^{1}, \\
& \\
& \tilde{X}_{H}^{1}, \tilde{X}_{H}^{2}, \tilde{X}_{H}^{D 1}, \tilde{X}_{H}^{D 2}, \tilde{Y}_{H}^{1}, \tilde{Y}_{H}^{2}, \tilde{Z}_{H}^{1}, \tilde{Z}_{H}^{2}, \tilde{\lambda}_{H}, \tilde{\pi}_{H} \geq 0
\end{align*}
$$

Given that $X_{\text {Total }}^{D 1}=N \bar{X}^{D 1}$ and $X_{\text {Total }}^{D 2}=N \bar{X}^{D 2}$, it is easy to see Model (13), which is the adjusted Model (12), using the new variables is exactly the same with Model (11). Therefore, the optimal solution to Model (11) is N times of that to Model (10). Thus, the proposition holds.

Based on the average input bundle, intermediate output/input bundle and output bundle from Step 2, setting

$$
\begin{aligned}
& \bar{P}^{S}=\left(Q^{1^{T}} \bar{Z}^{1}+Q^{3^{T}} \bar{Z}^{2}+Q^{2^{T}} \bar{Y}^{1}\right)-\left[\left(P^{1^{T}} \bar{X}^{1}+P^{2^{T}} \bar{X}^{D 1}\right)+\left(P^{1^{T}} \bar{X}^{2}+P^{3^{T}} \bar{X}^{D 2}+Q^{2^{T}} \bar{Y}^{2}\right)\right], \\
& \bar{P}^{L}=\left(Q^{1^{T}} \bar{Z}^{1}+Q^{2^{T}} \bar{Y}^{1}\right)-\left(P^{1^{T}} \bar{X}^{1}+P^{2^{T}} \bar{X}^{D 1}\right),, \\
& \bar{P}^{F}=Q^{3^{T}} \bar{Z}^{2}-\left(P^{P^{T}} \bar{X}^{2}+P^{3^{T}} \bar{X}^{D 2}+Q^{2^{T}} \bar{Y}^{2}\right) .
\end{aligned}
$$

Based on the optimal solution from Step 3, denote the total profit of the Bilevel system, the profit of the Leader and the profit of the Follower under the average input assumption by $P_{H}^{S}, P_{H}^{L}$ and $P_{H}^{F}$, respectively. Then
$P_{H}^{S}=\left(Q^{1^{T}} Z_{H}^{1^{*}}+Q^{3^{T}} Z_{H}^{2^{*}}+Q^{2^{T}} Y_{H}^{1^{*}}\right)-\left[\left(P^{1^{T}} X_{H}^{1^{*}}+P^{2^{T}} X_{H}^{D 1^{*}}\right)+\left(P^{1^{T}} X_{H}^{2^{*}}+P^{3^{T}} X_{H}^{D 2^{*}}+Q^{2^{T}} Y_{H}^{2^{*}}\right)\right]$,
$P_{H}^{L}=\left(Q^{1^{T}} Z_{H}^{1^{*}}+Q^{2^{T}} Y_{H}^{1^{*}}\right)-\left(P^{1^{T}} X_{H}^{1^{*}}+P^{2^{T}} X_{H}^{D 1^{*}}\right)$,
$P_{H}^{F}=Q^{3^{T}} Z_{H}^{2^{*}}-\left(P^{1^{T}} X_{H}^{2^{*}}+P^{3^{T}} X_{H}^{D 2^{*}}+Q^{2^{T}} Y_{H}^{2^{*}}\right)$.
Based on the optimal solution from Step 5, denote the total profit of the Bilevel system, the profit of the Leader and the profit of the Follower under merger assumption by $P_{M}^{S}, P_{M}^{L}$ and $P_{M}^{F}$, respectively. Then

$$
\begin{aligned}
& P_{M}^{S}=\left(Q^{1^{T}} Z_{M}^{1}+Q^{3^{T}} Z_{M}^{2}+Q^{2^{T}} Y_{M}^{1}\right)-\left[\left(P^{1^{T}} X_{M}^{1}+P^{2^{T}} X_{M}^{D 1}\right)+\left(P^{1^{T}} X_{M}^{2}+P^{3^{T}} X_{M}^{D 2}+Q^{2^{T}} Y_{M}^{2}\right)\right] \\
& P_{M}^{L}=\left(Q^{Q^{T}} Z_{M}^{1}+Q^{2^{T}} Y_{M}^{1}\right)-\left(P^{1^{T}} X_{M}^{1}+P^{2^{T}} X_{M}^{D 1}\right) \\
& P_{M}^{F}=Q^{3^{T}} Z_{M}^{2}-\left(P^{1^{T}} X_{M}^{2}+P^{3^{T}} X_{M}^{D 2}+Q^{2^{T}} Y_{M}^{2}\right)
\end{aligned}
$$

The merger efficiency of the whole Bilevel system is measured in Wu and Birge (2011) as

$$
\begin{equation*}
E_{m}^{S}=\frac{P_{M}^{S}}{N \cdot \bar{P}^{S}}=\frac{P_{H}^{S}}{\bar{P}^{S}} \cdot \frac{P_{M}^{S}}{N \cdot P_{H}^{S}}=H^{S} \cdot S^{S} \tag{14}
\end{equation*}
$$

where $H^{S}=\frac{P_{H}^{S}}{\bar{P}^{S}}$ represents the harmony effect and $S^{S}=\frac{P_{M}^{S}}{N P_{H}^{S}}$ represents the scale effect.
Similarly, the merger efficiency, harmony effect and scale effect of the Leader and the Follower can be defined. Denote the merger efficiency, harmony effect and scale effect of the Leader by $E_{m}^{L}, H^{L}$ and $S^{L}$. Denote the merger efficiency, harmony effect and scale effect of the Follower by $E_{m}^{F}, H^{F}$ and $S^{F}$.

If $E_{m}$ is greater than 1 , the N merger members will benefit from the potential profit generated by the merger, otherwise, it would be more efficient to keep them separate. The harmony effect measures the ratio between the profit gained under the average input assumption and the average profit of N individual merger members prior to the merger.

From Proposition 4, we can get that $P_{M}^{S}=N P_{H}^{S}, P_{M}^{L}=N P_{H}^{L}$ and $P_{M}^{S}=N P_{H}^{S}$ which indicate the scale effect $S$ should equal to 1 under the CRS assumption. Then we can further get that the merger efficiency $E_{m}$ equals to the harmony effect $H$ under the CRS assumption.
The scale effect may be less than, equal to or greater than 1. If the score of the scale effect is greater than 1 , the potential profit from the merger will be more than the sum of the profit produced by each member using the average input bundle.

## Chapter 5

## Two numerical studies

### 5.1 The first numerical example

To illustrate the theoretic findings, the following Bilevel decision example is solved by use of the model and algorithm proposed in this thesis. In this example, there are 8 branches in all, and each one can be seen as a DMU facing a hierarchical optimization problem consisting of two levels, the Leader's level and the Follower's level, and the framework of this hierarchical optimization problem is shown below in Fig. 3.

Fig. 3 The framework of Bilevel programming problem in the $1^{\text {st }}$ example
In order to test our proposed approach better, the data is created at random and is made more complex. For the Leader, we employ three inputs (two direct inputs $X^{D 1}$ and one shared input $X^{1}$ ) and three outputs (two direct outputs $Z^{1}$ and one intermediate output $Y$ ). For the follower, we utilize four inputs (two direct inputs $X^{D 2}$, one shared input $X^{2}$ and one intermediate input $Y$ ) and two direct outputs $Z^{2}$. The input and output data is exhibited in Table 1. Denote the profit of the Leader and the Follower by $P^{L}$ and $P^{F}$ respectively. And all of the unit price vectors to the inputs and outputs are set to be unit.

Table 1 The input and output data for the 8 branches in the $1^{\text {st }}$ example

| Branch | $X^{D 1}$ |  | $X^{1}$ | $Z^{1}$ |  | $Y$ | $X^{D 2}$ |  | $X^{2}$ | $Z^{2}$ |  | $P^{L}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| DMU1 | 2.5 | 13 | 4 | 35 | 60 | 30 | 1.5 | 12 | 16 | 55 | 65 | 105.5 |
| DMU2 | 7 | 12 | 13.4 | 76 | 53 | 55 | 5.6 | 13 | 6.6 | 87 | 45 | 151.6 |
| DMU3 | 3 | 7 | 9.8 | 52 | 42 | 40 | 4 | 15.4 | 10.2 | 65 | 56 | 114.2 |
| DMU4 | 9 | 18 | 4.6 | 63 | 71 | 70 | 8.8 | 11.2 | 15.4 | 78 | 89 | 172.4 |

### 5.1.1 Pre-merger

Considering the two situations we discussed above in this thesis.
Under the first situation, we investigate the profit efficiency of the system, the Leader and the Follower using Model (5), under the constant returns-to-scale (CRS) and variable returns-to-scale (VRS) assumptions respectively. We write the programs using Matlab language, first we set the observed input and output data and the unit price vectors to the inputs and outputs, second define the objective functions of the Leader and the Follower, third set the coefficient matrixes based on the constrains, last the extended branch and bound algorithm proposed by Shi et al. (2006) is implemented to solve the optimization problem, finally, the profit efficiency values of the Leader, the Follower and the system are computed. But the extended branch and bound algorithm is sometimes found to be ineffective when there are large numbers of variables involved in the model. In this case, instead, we use the Matlab optimization toolbox function fmincon to solve constrained nonlinear optimization problem.
Table 2 lists the CRS and VRS DEA profit efficiency values of the whole system and the two sublevels. It is worth remarking that the DEA profit efficiency values under CRS assumption are greater than those under VRS assumption, which is consistent with current existing DEA literature (Cooper et al., 2000). None of the systems are efficient under CRS assumption but 4 are efficient under VRS assumption. We also find that the whole system is efficient only when both of the sublevels are efficient, which is consistent with our Proposition 3. It can be seen that the profit efficiency of every Follower is 1 under both assumptions, but the profit efficiency of the whole system is not always 1 , which implies that during the profit optimizing process, most of the potential improvement profit is obtained by the Leader, which is the dominant level.

Table 2 Profit efficiency scores under both CRS and VRS models in the $1^{\text {st }}$ situation

| Branch | CRS |  |  | VRS |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $P E^{L}$ | $P E^{F}$ | $P E^{S}$ | $P E^{L}$ | $P E^{F}$ | $P E^{S}$ |
| DMU1 | 0.936 | 1 | 0.958 | 1 | 1 | 1 |
| DMU2 | 0.86 | 1 | 0.892 | 0.883 | 1 | 0.908 |
| DMU3 | 0.947 | 1 | 0.963 | 0.95 | 1 | 0.965 |
| DMU4 | 0.881 | 1 | 0.91 | 1 | 1 | 1 |
| DMU5 | 0.958 | 1 | 0.971 | 1 | 1 | 1 |
| DMU6 | 0.808 | 1 | 0.85 | 0.939 | 1 | 0.954 |
| DMU7 | 0.988 | 1 | 0.992 | 1 | 1 | 1 |
| DMU8 | 0.821 | 1 | 0.86 | 0.975 | 1 | 0.981 |

The optimized solutions for each DMU to be efficient under CRS and VRS assumptions are reported in Table 21 and Table 22 respectively in Appendix II.

Under the second situation, where the positions of the Leader and the Follower are swapped, we calculate the profit efficiency again. Table 3 documents the profit efficiency scores under both the CRS and VRS assumptions. And we can also find that the profit efficiency of every new Follower is 1 but one exception under both assumptions, meanwhile the profit efficiency of the system is not always 1 . It reflects that during the profit optimizing process, most of the potential improvement profit is still obtained by the dominant level, the new Leader.

Table 3 Profit efficiency scores under both CRS and VRS models in the $2^{\text {nd }}$ situation

| Branch | CRS |  |  | VRS |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $P E^{L}$ | $P E^{F}$ | $P E^{S}$ | $P E^{L}$ | $P E^{F}$ | $P E^{S}$ |
| DMU1 | 0.894 | 1 | 0.958 | 1 | 1 | 1 |
| DMU2 | 0.800 | 1 | 0.940 | 0.998 | 0.963 | 0.972 |
| DMU3 | 0.890 | 1 | 0.963 | 0.894 | 1 | 0.965 |
| DMU4 | 0.869 | 1 | 0.962 | 1 | 1 | 1 |
| DMU5 | 0.916 | 1 | 0.971 | 1 | 1 | 1 |
| DMU6 | 0.732 | 1 | 0.914 | 0.842 | 1 | 0.954 |
| DMU7 | 0.976 | 1 | 0.992 | 1 | 1 | 1 |
| DMU8 | 0.796 | 1 | 0.939 | 0.93 | 1 | 0.981 |

The corresponding optimized solutions for each DMU under this condition to be efficient under CRS and VRS assumptions are reported in Table 23 and Table 24 respectively in Appendix II.

### 5.1.2 $\alpha$-Strategy

Obviously, the reciprocal of the efficiency shows the promotion from the observed profit. For example, if the efficiency is 0.8 , the reciprocal of the efficiency is 1.25 . There is $25 \%$ of potential improvement from the observed profit. And it is clear to see that dominant level (the Leader) gains much more potential improvement profit than what the lower level (the Follower) gains. Thus the hierarchical structure is not steady.

To encourage the Follower to participate, the Leader promises to share $\alpha$ of his profit to the Follower which is called $\alpha$-Strategy. Therefore, the total profit that the Follower would get is his actual profit plus $\alpha$ of the Leader's profit. The total profit of the system remains unchanged under this $\alpha$-Strategy.

Under the first situation with CRS assumption which we proposed above, in order to find a suitable $\alpha$ for the Leader under this strategy, we calculate the efficiency ratio between the Leader's adjusted optimized profit and the observed profit in Fig. 4, and the efficiency ratio between the Follower's adjusted optimized profit and the observed profit in Fig. 5 when $\alpha$ changes from 0 to 0.1 with 0.01 increment.

## Efficiency ratio

Fig. 4 The efficiency ratio of the Leader under $\alpha$-strategy

## Efficiency ratio

Fig. 5 The efficiency ratio of the Follower under $\alpha$-strategy

From these two figures as well as the conception of $\alpha$-Strategy, it is obvious that the efficiency ratio of the Leader decreases with the growth of $\alpha$, while the efficiency ratio of the Follower increases with the growth of $\alpha$. To ensure the benefit of the Leader, the efficiency ratio of the Leader must be greater than or equal to 1 . Thus the value of $\alpha$ is set to be 0.01 based on Fig. 4 in this case. Under $\alpha$-strategy with $\alpha=0.01$, the optimized profit of the system, the Leader and the Follower and the observed profit of them are listed in Table 4. In this table, the optimized profits of the system, the Leader and the Follower are all improved comparing to the observed profits for each branch.

Table 4 The optimized profit and the observed profit with $\alpha=0.01$

| Branch | Observed <br> Leader profit | Optimized <br> profit of the <br> Leader | Observed <br> Follower <br> profit | Optimized <br> profit of the <br> Follower | Observed <br> system profit | Optimized <br> profit of the <br> system |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| DMU1 | 105.5 | 111.569 | 60.5 | 61.627 | 166 | 173.196 |
| DMU2 | 151.6 | 174.449 | 51.8 | 53.562 | 203.4 | 228.011 |
| DMU3 | 114.2 | 119.337 | 51.4 | 52.605 | 165.6 | 171.942 |
| DMU4 | 172.4 | 193.646 | 61.6 | 63.556 | 234 | 257.202 |
| DMU5 | 110.2 | 113.907 | 53.1 | 54.251 | 163.3 | 168.158 |
| DMU6 | 142.9 | 175.099 | 49.2 | 50.969 | 192.1 | 226.068 |
| DMU7 | 119 | 119.223 | 57.4 | 58.604 | 176.4 | 177.827 |
| DMU8 | 170.3 | 205.327 | 57.5 | 59.574 | 227.8 | 264.901 |

### 5.1.3 Post merger

For the purpose of considering potential mergers, we examine what potentially profit could be gained by merging each pair of branches. This leads to a total of 28 possible mergers. Therefore, the relative profit efficiency of these 28 possible mergers is computed with reference to the original DMU by our Bilevel programming DEA model.
According to the two situations we proposed above, the merger, the harmony effect and the scale effect are evaluated respectively under both CRS and VRS assumptions. The numbers of the effective mergers are listed in Table 5.
Table 5 indicates that the number of the effective mergers for the dominate level is always greater than that for the other level. Thus it implies that the dominate level tends to favor merger much more than the other does in this case.

Table 5 The numbers of the effective mergers under both CRS and VRS assumptions

|  | Merger efficiency measures(>100\%) | number under CRS | number under VRS |
| :---: | :---: | :---: | :---: |
| $1^{\text {st }}$situation | effective mergers for the Leader | 20 | 3 |
|  | effective mergers for the Follower | 8 | 2 |
|  | effective mergers for the whole system | 18 | 3 |
| $2^{\text {nd }}$ situation | effective mergers for the new Leader | 24 | 12 |
|  | effective mergers for the new Follower | 9 | 0 |
|  | effective mergers for the whole system | 20 | 12 |

In the first situation, 20 mergers are found to be efficient from the Leader's perspective among the total 28 mergers under CRS assumption. And we have proved that merger efficiency $E_{m}$ equals to harmony effect $H$ in this case. Table 6 lists the top 10 most promising mergers from the Leader's perspective.

Table 6 The top 10 promising mergers in the $1^{\text {st }}$ situation under CRS

| Merger | $E_{m}^{L}=H^{L}$ | $E_{m}^{F}=H^{F}$ | $E_{m}^{S}=H^{S}$ |
| :---: | :---: | :---: | :---: |
| 4,5 | 1.125 | 0.999 | 1.092 |
| 3,4 | 1.098 | 0.999 | 1.072 |
| 5,8 | 1.09 | 1.001 | 1.067 |
| 4,7 | 1.081 | 1.001 | 1.059 |
| 3,8 | 1.06 | 1.001 | 1.045 |
| 1,4 | 1.059 | 0.999 | 1.042 |
| 1,8 | 1.057 | 0.999 | 1.041 |
| 7,8 | 1.047 | 0.999 | 1.035 |
| 5,6 | 1.042 | 0.999 | 1.031 |
| 4,6 | 1.035 | 1.001 | 1.027 |

The merger efficiencies in the first row indicate that the profit of the Leader will increase by $12.5 \%$, the total profit of the system will increase by $9.2 \%$, and the profit of the Follower will decrease by $0.1 \%$, if the merger of DMU 4 and DMU 5 induces best practice. We can find that among these 10 mergers, none of the Followers benefit much from the merger. And a merger is regarded to be coordinated effective only when merger efficiency scores of the Leader, the Follower and the whole Bilevel system are all greater than 1 . Based on this definition, we find that there are 6 coordinated effective mergers. And these promising coordinated mergers are listed in Table 7.

Table 7 The promising coordinated mergers in the $1^{\text {st }}$ situation under CRS

| Merger | $E_{m}^{L}=H^{L}$ | $E_{m}^{F}=H^{F}$ | $E_{m}^{S}=H^{S}$ |
| :---: | :---: | :---: | :---: |
| 5,8 | 1.09 | 1.001 | 1.067 |
| 4,7 | 1.081 | 1.001 | 1.059 |
| 3,8 | 1.06 | 1.001 | 1.045 |
| 4,6 | 1.035 | 1.001 | 1.027 |
| 6,8 | 1.023 | 1.001 | 1.018 |
| 2,8 | 1.014 | 1.001 | 1.011 |

Under the VRS assumption, only 3 mergers are efficient from the Leader's perspective. The merger scores of them are shown in Table 8. For example, the merger of branch 2 and branch 6 has a merger efficiency value of 1.084 from the Leader's perspective, which implies that merger of these two separate branches would gain 4.6\% more profit than the combined profits of these two branches using their individual input bundles respectively, from the Leader's perspective. The harmony effect of the Leader shows that these two branches, each using the average input bundles, will together gain $15.5 \%$ more profit than what they would gain collectively using their individual input bundles. The scale effect of the system, which is 0.921 , indicates that a single branch using twice the average input bundle would gain $7.9 \%$ lower profit than the combined profits of these two branches if each uses the average input bundles. However, in this case the positive harmony effect dominates the negative scale effect from the whole system's perspective. And it is easy to see that from the Follower's perspective, the negative scale effect dominates the positive harmony effect, which leads to an ineffective merger for the Follower. In conclusion, we find that none of these 3 mergers is coordinated effective.

Table 8 The effective mergers in the $1^{\text {st }}$ situation under VRS

| Merger | $E_{m}^{L}$ | $H^{L}$ | $S^{L}$ | $E_{m}^{F}$ | $H^{F}$ | $S^{F}$ | $E_{m}^{S}$ | $H^{S}$ | $S^{S}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2,6 | 1.118 | 1.155 | 0.921 | 0.996 | 1.004 | 0.97 | 1.084 | 1.112 | 0.933 |
| 2,7 | 1.027 | 1.189 | 0.868 | 0.996 | 1.01 | 0.987 | 1.017 | 1.13 | 0.903 |
| 2,3 | 1.012 | 1.156 | 0.884 | 0.996 | 0.996 | 0.995 | 1.007 | 1.106 | 0.916 |

Furthermore, we depict the scores of both harmony and scale effect of the Leader under VRS assumption in Fig. 6. From the figure, it is easy to see that the scores of harmony effect are greater than 1 , however scale effect is ineffective from merger.

Fig. 6 The VRS scores of both harmony and scale effects of the Leader
In the second situation, where the positions of the Leader and the Follower are swapped, under CRS assumption, 24 mergers are found to be efficient from the new Leader's perspective and 6 of them are coordinated effective. Table 9 lists the top 10 most promising mergers from the new Leader's perspective. From the table, we can find that only 2 of these 10 mergers are coordinated effective.

Table 9 The top 10 promising mergers in the $2^{\text {nd }}$ situation under CRS

| Merger | $E_{m}^{L}=H^{L}$ | $E_{m}^{F}=H^{F}$ | $E_{m}^{S}=H^{S}$ |
| :---: | :---: | :---: | :---: |
| 3,4 | 1.094 | 1.001 | 1.029 |
| 3,8 | 1.093 | 0.999 | 1.029 |
| 2,5 | 1.083 | 0.999 | 1.027 |
| 4,5 | 1.079 | 1.001 | 1.025 |
| 5,8 | 1.078 | 0.999 | 1.025 |
| 4,7 | 1.074 | 0.999 | 1.023 |
| 7,8 | 1.073 | 0.999 | 1.023 |
| 3,6 | 1.071 | 0.999 | 1.023 |
| 2,3 | 1.063 | 0.999 | 1.021 |
| 6,7 | 1.058 | 0.999 | 1.019 |

Under the VRS assumption, 12 mergers are effective from the new Leader's perspective, but none is effective from the new Follower's perspective, which means the Leader benefits much more from the merger than the Follower in this case. The merger scores of the top 10 most promising mergers from the new Leader's perspective are shown in Table 10.

Table 10 The top 10 promising mergers in the $2^{\text {nd }}$ situation under VRS

| Merger | $E_{m}^{L}$ | $H^{L}$ | $S^{L}$ | $E_{m}^{F}$ | $H^{F}$ | $S^{F}$ | $E_{m}^{S}$ | $H^{S}$ | $S^{S}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2,5 | 2.566 | 2.792 | 0.919 | 0.999 | 1 | 0.999 | 1.172 | 1.197 | 0.979 |
| 2,7 | 2.326 | 2.783 | 0.836 | 0.999 | 1 | 0.999 | 1.158 | 1.212 | 0.955 |
| 2,6 | 2.204 | 2.954 | 0.746 | 0.999 | 1 | 0.999 | 1.136 | 1.222 | 0.93 |
| 2,3 | 2.11 | 2.613 | 0.808 | 0.999 | 1 | 0.999 | 1.134 | 1.196 | 0.949 |
| 1,5 | 2.083 | 1.89 | 1.102 | 0.999 | 1 | 0.999 | 1.236 | 1.194 | 1.035 |
| 1,4 | 1.738 | 1.77 | 0.982 | 0.999 | 1 | 0.999 | 1.146 | 1.152 | 0.994 |
| 1,8 | 1.736 | 1.75 | 0.992 | 0.999 | 1 | 0.999 | 1.147 | 1.15 | 0.997 |
| 1,3 | 1.669 | 1.713 | 0.974 | 0.999 | 1.007 | 0.993 | 1.151 | 1.167 | 0.987 |
| 1,2 | 1.639 | 1.739 | 0.942 | 0.999 | 1 | 0.999 | 1.117 | 1.135 | 0.984 |
| 1,7 | 1.571 | 1.831 | 0.858 | 0.999 | 1 | 0.999 | 1.127 | 1.185 | 0.951 |

### 5.2 The second numerical example

In the second example, we use the data from Wu and Birge (2011), regarding 30 branches from a large Canadian Mortgage bank, and the input-output framework is demonstrated in Fig. 7. And obviously it is also a hierarchical system with two levels.

Fig. 7. The framework of Bilevel programming problem in the $2^{\text {nd }}$ numerical example
The data includes two direct inputs: Personal Costs and Other Expenses, one shared input: IT Budget for both the Leader and Follower, one intermediate output: loans and two outputs: profit and Loan recovery. Assuming the variables equally important by the decision makers, all unit price vectors of them are set to be unit. Raw data for the inputs and outputs are shown in Table 11. And the data in this table is unified into one magnitude: $10^{5}$.

Table 11 Raw data of 30 branches in the $2^{\text {nd }}$ example

| Branch | $X^{\text {D1 }}$ |  | $X^{1}$ | $Y$ | $X^{2}$ | $Z^{2}$ |  | $\begin{gathered} P^{L} \\ \left(\times 10^{5}\right) \end{gathered}$ | $\begin{gathered} P^{F} \\ \left(\times 10^{5}\right) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Other <br> Expense <br> $\left(\times 10^{5}\right)$ | Personal <br> Cost <br> $\left(\times 10^{5}\right)$ | IT <br> Budget <br> $\left(\times 10^{5}\right)$ | $\begin{gathered} \text { Loan } \\ \left(\times 10^{5}\right) \end{gathered}$ | IT <br> Budget <br> $\left(\times 10^{5}\right)$ | $\begin{aligned} & \text { Profit } \\ & \left(\times 10^{5}\right) \end{aligned}$ | Loan Recovery $\left(\times 10^{5}\right)$ |  |  |
| DMU1 | 71.3 | 1.5 | 0.133 | 1447.8 | 2.5 | 523.2 | 1427.7 | 1374.9 | 500.6 |
| DMU2 | 107.1 | 1.7 | 0.169 | 1950.2 | 2.3 | 534 | 1923.3 | 1841.2 | 504.8 |

### 5.2.1 Pre-merger

Considering the two situations we discussed above in this thesis.
Under the first situation, we investigate the profit efficiency of the system, the Leader and the Follower of these 30 branches using Model (5), under the CRS and VRS assumptions respectively. The results of the profit efficiency scores are listed in Table 12. And we figure the result in Fig. 8.

Table 12 Profit efficiency scores under both CRS and VRS models in the $1^{\text {st }}$ situation

| Branch | CRS |  |  | VRS |  |  |

Fig. 8. The profit efficiency scores in the $1^{\text {st }}$ situation
From Fig. 8, the DEA profit efficiency values under CRS assumption are still found to be greater than those under VRS assumption. And we also find that profit efficiency scores of the system are close to those of the Leader. But profit efficiency scores of the Follower are found to be distinctive from those of the system. In short, the profit efficiency of the system is mainly affected by the profit efficiency of the Leader under this situation.

In the second situation, the profit efficiency of the system, the new Leader and the new Follower is evaluated using Model (6), under both CRS and VRS assumptions. The results are depicted in Fig. 9, and the profit efficiency scores are shown in Table 13.

Fig. 9. The profit efficiency scores in the $2^{\text {nd }}$ situation

Table 13 Profit efficiency scores under both CRS and VRS models in the $2^{\text {nd }}$ situation

| DMU29 | 1 | 0.589 | 0.873 | 0.946 | 0.994 | 0.956 |
| DMU30 | 0.796 | 0.402 | 0.684 | 0.716 | 0.945 | 0.735 |
|  |  |  |  |  |  |  |

To further investigate the profit efficiency, we figure the profit efficiency scores of the Leaders in these two situations together in Fig. 10.

Fig. 10 The profit efficiency scores of the Leaders in the two situations
From Fig. 10, it can be seen that most of the profit efficiency scores of the Leaders in the second situation are slight higher, which means the potential improvement from the observed profit under the second situation is a little less than that under the first situation.

The profit efficiency scores of the Followers in these two situations are shown together in Fig. 11.

Fig. 11 The profit efficiency scores of the Followers in the two situations
It is clear to see that the Followers get lower profit efficiency scores in the second situation comparing with the other one. It implies that the Followers can benefit more potential profit from the DEA optimization process in the second situation.
Thus we infer that the both the Leader and Follower must favor the situation, where they are at the dominant level.

### 5.2.2 Post merger

For the purpose of considering potential mergers, we examine what potentially profit could be gained by merging each two branches. And this leads to totally 435 possible mergers. Therefore, the relative profit efficiency of these 435 possible mergers is computed with reference to the original DMU by our Bilevel programming DEA model.

According to the two situations we proposed above, the merger, the harmony effect and the scale effect are evaluated respectively under both CRS and VRS assumptions. The numbers of the effective mergers and the average merger efficiency scores $\bar{E}_{m}$ are listed in Table 14.

Table 14 The numbers of the effective mergers under both CRS and VRS assumptions

|  |  | CRS |  | VRS |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | number | $\bar{E}_{m}$ | number | $\bar{E}_{m}$ |
|  | effective mergers for the Leader | 218 | 1.023 | 213 | 1.779 |
|  | effective mergers for the Follower | 191 | 1.02 | 13 | 1 |
|  | effective mergers for the whole system | 225 | 1.022 | 213 | 1.61 |
| $2^{\text {nd }}$ | effective mergers for the new Leader | 299 | 1 | 70 | 1 |
|  | effective mergers for the new Follower | 249 | 1.035 | 113 | 1.263 |
|  | effective mergers for the whole system | 335 | 1.007 | 112 | 1.194 |

Table 14 indicates that there are numerous mergers effective under CRS assumption, and relatively fewer under VRS assumption. And the results of the average merger efficiency scores $\bar{E}_{m}$ show significant gains from mergers and relatively higher under VRS assumption.

Based on the concept of the coordinated effective merger, which we have defined in the first numerical example, the numbers of coordinated effective mergers in two situations under both CRS and VRS assumptions are exhibited in Table 15.

Table 15 The number of the coordinated effective mergers

|  | number under CRS | number under VRS |
| :---: | :---: | :---: |
| $1^{\text {st }}$ situation | 163 | 7 |
| $2^{\text {nd }}$ situation | 193 | 3 |

From Table 15, it can be seen that the number of the coordinated effective mergers under CRS assumption are much more than those under VRS assumption in all these two situations. Especially, $44.3 \%$ of the total 435 mergers, which are 193 mergers, are coordinated effective under CRS in the second situation.

In the first situation, 218 mergers are found to be efficient from the Leader's perspective and $74.8 \%$ of them, which are 163 mergers, are coordinated effective. Table 16 lists the top 10 most promising mergers for the Leader. It is easy to see that all of these 10 mergers are coordinated effective, so it is recommended to achieve them since both of the members obtain potential gains from the merger. And it is worth to mention that the Leaders benefit much more from the merger than the Followers among these top 10 promising coordinated mergers.

Table 16 The top 10 promising mergers in the $1^{\text {st }}$ situation under CRS

| Merger | $E_{m}^{L}=H^{L}$ | $E_{m}^{F}=H^{F}$ | $E_{m}^{S}=H^{S}$ |
| :---: | :---: | :---: | :---: |
| 22,23 | 1.327 | 1.138 | 1.253 |
| 2,22 | 1.188 | 1.051 | 1.146 |
| 2,23 | 1.186 | 1.056 | 1.147 |
| 22,29 | 1.173 | 1.061 | 1.138 |
| 16,22 | 1.155 | 1.005 | 1.109 |
| 16,23 | 1.147 | 1.055 | 1.119 |
| 4,22 | 1.137 | 1.001 | 1.095 |
| 17,23 | 1.132 | 1.076 | 1.112 |
| 17,22 | 1.129 | 1.076 | 1.111 |
| 13,23 | 1.106 | 1.019 | 1.081 |

There are 213 merger efficiency scores of the Leader are larger than 1 under the VRS assumption in the first situation, however only 7 of these mergers are found coordinated effective. The top 10 promising mergers from the Leader's perspective in the first situation under VRS assumption are listed in Table 17.

Table 17 The top 10 promising mergers in the $1^{\text {st }}$ situation under VRS

| Merger | $E_{m}^{L}$ | $H^{L}$ | $S^{L}$ | $E_{m}^{F}$ | $H^{F}$ | $S^{F}$ | $E_{m}^{S}$ | $H^{S}$ | $S^{S}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 5,24 | 4.111 | 1 | 4.111 | 0.996 | 1 | 0.996 | 3.334 | 1 | 3.333 |
| 5,27 | 4.084 | 1.237 | 3.3 | 0.997 | 1 | 0.997 | 3.335 | 1.18 | 2.827 |
| 20,22 | 3.867 | 1.295 | 2.985 | 0.997 | 1 | 0.997 | 3.087 | 1.215 | 2.54 |
| 1,5 | 3.715 | 1.212 | 3.064 | 0.997 | 1 | 0.996 | 3.1 | 1.164 | 2.662 |
| 22,30 | 3.48 | 1.261 | 2.76 | 0.998 | 1 | 0.998 | 2.947 | 1.205 | 2.446 |
| 24,27 | 3.398 | 1.11 | 3.063 | 0.996 | 1 | 0.996 | 2.851 | 1.085 | 2.628 |
| 17,30 | 3.311 | 1.116 | 2.966 | 0.998 | 1 | 0.998 | 2.836 | 1.092 | 2.596 |
| 1,17 | 3.213 | 1.002 | 3.208 | 0.999 | 1 | 0.999 | 2.655 | 1.001 | 2.652 |
| 23,29 | 3.168 | 1.137 | 2.786 | 0.997 | 1.001 | 0.997 | 2.639 | 1.104 | 2.39 |
| 16,22 | 3.136 | 1.088 | 2.882 | 0.997 | 1 | 0.997 | 2.629 | 1.068 | 2.463 |

Furthermore, under VRS assumption in the first situation, to examine the harmony effect and the scale effect, we depict the scores of them of the Leader in Fig. 12. From the figure, it is easy to see that the scores of harmony effect are greater than 1 , however some of scale effect scores are greater than 1 and some of them are less than 1. And it means the scale effect is ineffective from merger when the scale effect score is less than 1 .

Fig. 12 The VRS scores of both harmony and scale effects of the Leader in the $1^{\text {st }}$ situation
In the second situation, where the positions of the Leader and the Follower are swapped, under CRS assumption, 299 mergers are found to be efficient from the new

Leader's perspective and 193 coordinated effective mergers are found. Table 18 lists the top 10 most promising mergers from the new Leader's perspective. And it is easy to show that all of these 10 mergers are coordinated effective.

Table 18 The top 10 promising mergers in the $2^{\text {nd }}$ situation under CRS

| Merger | $E_{m}^{L}=H^{L}$ | $E_{m}^{F}=H^{F}$ | $E_{m}^{S}=H^{S}$ |
| :---: | :---: | :---: | :---: |
| 15,29 | 1.047 | 1.033 | 1.001 |
| 21,29 | 1.027 | 1.019 | 1.001 |
| 15,23 | 1.002 | 1.002 | 1.004 |
| 14,23 | 1.001 | 1.031 | 1.111 |
| 15,17 | 1.001 | 1.002 | 1.005 |
| 28,29 | 1.001 | 1.001 | 1.003 |
| 15,24 | 1.001 | 1.002 | 1.006 |
| 21,25 | 1.001 | 1.001 | 1.005 |
| 13,21 | 1.001 | 1.001 | 1.004 |
| 12,16 | 1.001 | 1.009 | 1.036 |

There are 70 merger efficiency scores of the new Leader larger than 1 under the VRS assumption in the second situation, but only 3 of these mergers are found coordinated effective. The top 10 promising mergers from the new Leader's perspective in the first situation under VRS assumption are listed in Table 19. And the 3 coordinated effective mergers are shown in Table 20.

Table 19 The top 10 promising mergers in the $2^{\text {nd }}$ situation under VRS

| Merger | $E_{m}^{L}$ | $H^{L}$ | $S^{L}$ | $E_{m}^{F}$ | $H^{F}$ | $S^{F}$ | $E_{m}^{S}$ | $H^{S}$ | $S^{S}$ |

## Chapter 6

## Conclusions, limitations and future research

Within the recent two decades, many real operation problems are modeled into a hierarchical structure, where more than one player is involved. Bilevel programming is a very useful tool to solve the special optimization problems which consist of two objectives, one is the Leader's, and the other is Follower's. The Leader is at the dominant level and the Follower is at the submissive level. As we already know, Bilevel programming is applied in many fields. In this thesis, we develop a Bilevel programming DEA model to evaluate the profit efficiency of the systematic and sub-unit levels under both CRS and VRS assumptions. The resources are limited which often happens in reality. The results demonstrate that the sub-level benefits more potential profit from the Bilevel programming DEA optimization process when sub-level is in the dominant level, but not at the submissive level.

The system is found to be efficient only if sub-levels are both efficient. In order to stabilize the hierarchical structure, $\alpha$-Strategy is proposed here to stimulate the follower to actively participate.

Expecting potential gains from merger, we build new models to evaluate the merger efficiency under both CRS and VRS assumptions, and decompose the merger efficiency into harmony effect and scale effect. The applicability of the proposed approach is further illustrated in two case studies: a numerical example and a practical example about the branches in a big Canadian bank are conducted. The results indicate considerable potential gains from the promising mergers and relative higher potential gains under the VRS assumption. The concept of coordinated effective merger is also discussed, and it is very important since every member in the system benefits from the merger.

The limitations of this study are that internal relationship of the two situations and the differences of the total profit of the system under these two situations are not deeply investigated. During the computation process, the extended branch and bound algorithm is sometimes found to be ineffective when there are large numbers of variables involved in the model.

Nevertheless, future research about Bilevel programming DEA with bounded output is suggested, taking into account the maximum capacity of the output. Future extension of our merger study could examine the effects of the type of the merger, and the method of financing, and the stock-price returns of the merger-involved firms, both pre-merger and post-merger. Especially, Markov-regime-switching GARCH models are recommended to characterize the takeover or merger process.
